#### **1** Introduction and Summary

In October 2019, Assembly Bill (AB) 1400 was signed into law requiring the California Department of Industrial Relations (DIR) Commission on Health and Safety and Worker's Compensation (CHSWC) to submit a study to the Legislature, the Occupational Safety and Health Standards Board, and the Los Angeles County Board of Supervisors on the risk of exposure to carcinogenic materials and incidence of occupational cancer in mechanics who repair and clean firefighting vehicles. Specifically, AB 1400 required that the study include:

- 1. Site visits at a representative sample of facilities, including, but not limited to, facilities in the County of Los Angeles, where firefighting equipment is cleaned and repaired.
- 2. Interviews and surveys with current and former mechanics of firefighting equipment in a sample of facilities regarding the frequency of exposure to potential carcinogens, use and availability of safety equipment, and experience or knowledge of cancer incidence among current or former mechanics who cleaned or repaired firefighting equipment.
- 3. A measurement of the current levels of carcinogenic material exposure to mechanics who repair and clean firefighting vehicles in the County of Los Angeles and other facilities included in the study, in order to develop a baseline of carcinogenic material exposure.

The minimum scope of services, as stated in the request for proposal (RFP) #4479 "Assessment of Risk of Carcinogens Exposure and Incidents of Occupational Cancer among Mechanics and Cleaners of Firefighting Vehicles", further outlined the study requirements, including:

- 1. Conduct a thorough literature review of carcinogen exposures in fire stations and for firefighting vehicle mechanics and cleaners.
- 2. Site visits at a representative sample of facilities, including, but not limited to, facilities in the County of Los Angeles where firefighting equipment is cleaned and repaired;
- 3. Interviews and surveys with current and former mechanics of firefighting equipment in a sample of facilities regarding the frequency of exposure to potential carcinogens, use and availability of safety equipment, and experience or knowledge of cancer incidence among current or former mechanics who cleaned or repaired firefighting equipment. In particular, a detailed questionnaire administered in person to current and former mechanics and cleaners of firefighter equipment combined with industrial hygiene surveys should be employed as part of the study;
- 4. A measurement of the current levels of exposure to (unspecified) carcinogenic material among mechanics who repair and clean firefighting vehicles in the County of Los Angeles and other facilities included in the study, in order to develop a baseline of carcinogenic material exposure;

5. In addition to conducting an assessment of the risk of carcinogens exposure and incidents of occupational cancer among mechanics and cleaners of firefighting vehicles, the vendor will respond to DIR requests for technical assistance on legislative and/or regulatory issues related to the assessment of carcinogen exposures to mechanics and cleaners of firefighting equipment.

ToxStrategies, Inc., (ToxStrategies) was contracted by CHSWC, to conduct the study as outlined in AB 1400 and RFP #4479. This report summarizes the effort to complete the study since June 2020.

#### 1.1 Summary of Study Activities

The following activities were performed to implement this study to address the questions raised in the legislation.

Task 1: Structured Literature Review of Potential Occupational Exposures and Cancers among Mechanics Who Repair and Clean Firefighting Vehicles — summary of available scientific literature on exposure to chemical carcinogens and studies of cancer risk among fire mechanics

- Task 2: Qualitative Exposure Assessment site visits at representative facilities
- Task 3: Epidemiology Feasibility Study feasibility study of cohort enumeration
- Task 4: Quantitative Exposure Assessment measurement of current occupational exposures to carcinogens
- Task 5: Cancer Risk Assessment calculation of theoretical excess cancer risks from occupational exposure to carcinogens

The subsequent sections of this report summarize the information obtained and results and conclusions developed for each of these tasks.

#### 1.2 Summary of Overall Study Results

While epidemiologic studies of cancer risk among firefighters and mechanics have been reported, no study to date has evaluated the risk of cancer among mechanics who repair and clean firefighting vehicles. The number of fire mechanics in Los Angeles (LA) County alone, with records dating back to 1975, is insufficient to evaluate the risk of cancer among fire mechanics in an epidemiological study. However, such a study may be possible if the potential cohort was expanded to include fire mechanics in other large counties in California.

In addition to the epidemiology feasibility study and consistent with the RFP, ToxStrategies performed a detailed qualitative (e.g., site visits, interviews and surveys with current and former fire mechanics) and quantitative (e.g., measurements of carcinogenic material) evaluation to assess LA County fire mechanics' occupational exposure to

chemical carcinogens. In September 2020, site visits were conducted at a representative sample of facilities in LA County, where firefighting equipment is cleaned and repaired:

- 1. Air Operations in Pacoima,
- 2. Breathing Apparatus Shop in Pacoima,
- 3. Eastern Fire Shop in Los Angeles, and
- 4. North County Fire Shop & Fire Station 129 in Lancaster

In November 2020, sampling of surface residues on fire equipment and personal breathing zone (PBZ) air samples were collected over two days at Air Operations, the Breathing Apparatus Shop, and the Eastern Fire Shop. Although the samples were collected on a single day at each location, worst-case exposure conditions were sampled to the extent possible (e.g., the most visibly contaminated surfaces were sampled). Toxicity criteria developed by California regulators were used in the assessment to estimate the theoretical increased cancer risk from the measured exposures.

Exposures to surface residues resulted in risks less than 1 in 10,000, which is the regulatory benchmark set by the National Institute of Occupational Safety and Health (NIOSH). The health risk assessment found that airborne exposures among fire mechanics in each of the studied operations resulted in a theoretical increased cancer risk that exceeds the NIOSH risk benchmark, and as such, improvements to working conditions in accordance with the NIOSH hierarchy of controls to reduce chemical exposures is recommended.

# 2 Structured Literature Review of Potential Occupational Exposures and Cancers among Mechanics Who Repair and Clean Firefighting Vehicles (Task 1)

The purpose of Task 1, Structured Literature Review, was to identify and review relevant published literature to understand the state of the science with respect to exposure to chemical carcinogens associated with repairing and cleaning firefighting vehicles and equipment, as well as studies of cancer risk among fire mechanics.

The objectives of the structured literature review were as follows:

- 1. Identify carcinogenic chemicals of potential concern (COPCs) for mechanics who repair and clean firefighting vehicles and equipment
- 2. Identify epidemiologic studies evaluating the risk of cancer among mechanics who repair and clean firefighting vehicles and equipment.

For the first objective of identifying studies reporting carcinogenic exposures experienced by fire mechanics, no occupational chemical exposure studies explicitly focused on fire mechanics, fire equipment cleaners, or firefighting vehicle maintenance workers. However, nine industrial hygiene studies presented data for fire stations and firefighting vehicles and/or gear, which likely overlap with the occupational exposures of fire

mechanics who repair and clean firefighting vehicles. Figure 1 presents a flow diagram showing the sequential search results of the literature search.

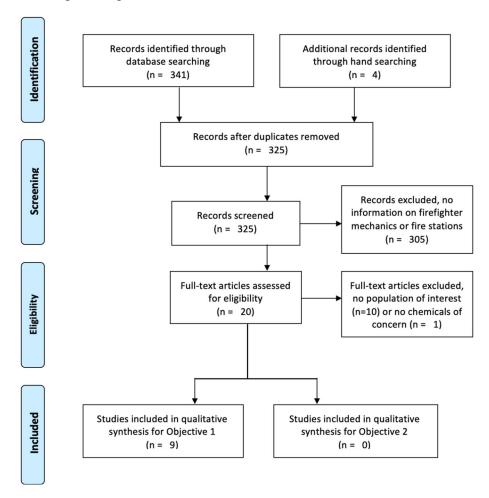

Figure 1. Literature search flow diagram.

The chemical carcinogens evaluated in these studies, which were included in the quantitative exposure assessment (Task 4), were benzene, diesel exhaust, polycyclic aromatic hydrocarbons (PAHs), crystalline silica, ethylbenzene, polychlorinated biphenyls (PCBs), acetaldehyde, formaldehyde, and styrene. A recent study, identified after the literature search was completed, identified chlorinated dioxins/furans; thus, chlorinated dioxins/furans were also included in the quantitative exposure assessment.

For the second objective of identifying studies of cancer risks or rates among fire mechanics, no epidemiologic studies were identified. A supplemental literature search was conducted to identify risk of cancer in the related occupations of firefighting and automotive maintenance and repair. Though a more thorough systematic review is necessary to fully characterize the risks in these occupations, our preliminary review of the International Agency for Research on Cancer (IARC) monographs and the supplemental literature demonstrated that certain cancers have been reported as increased in firefighters

and automotive mechanics as shown in Table 1. While the studies of firefighters and automotive mechanics provide additional insight into the risks associated with these related occupations, the results of these studies may not be generalizable to the experience of fire mechanics.

Table 1. Reported cancer types potentially associated with occupation in firefighting and automotive maintenance and repair

| Cancer Site or Type    | Secondary<br>Literature,<br>Auto Mechanics | Nordic Cohorts,<br>Auto Mechanics | IARC, Firefighters |
|------------------------|--------------------------------------------|-----------------------------------|--------------------|
| Bladder                | X                                          |                                   |                    |
| Lung                   |                                            | X                                 |                    |
| Mesothelioma           |                                            | X                                 |                    |
| Non-Hodgkin's Lymphoma |                                            | X                                 | X                  |
| Pancreas               |                                            | X                                 |                    |
| Prostate               |                                            |                                   | X                  |
| Testicular             |                                            |                                   | X                  |
| Ureter and Urethra     |                                            | X                                 |                    |

The findings from Task 1 structured literature review were informative with respect to potential chemical exposures that were evaluated in the qualitative (Task 2) and quantitative exposure assessments (Task 4).

The Task 1 report is attached as Appendix A.

#### **3** Qualitative Exposure Assessment (Task 2)

The purpose of Task 2, Qualitative Exposure Assessment, was to determine similar exposure groups (SEGs) among the fire mechanics and prioritize/define the scope of the quantitative exposure assessment based on a risk ranking that incorporates the relative magnitude of the exposure potential, specifically for carcinogens<sup>1</sup>. Each job task was characterized in terms of relevant chemical product usage information and/or fire residues encountered. The overall risk ranking was determined based on an exposure rating and health effect rating of the product and/or residue encountered by fire mechanics, by job task. Figure 2 shows the matrix that combines the exposure rating and health effect rating.

| 1               |                      | Low |          |      |           |
| 0               | Trivial              |     |          |      |           |

Figure 2. Risk ranking matrix

Task 2 was accomplished through site visits to representative facilities, interviews and surveys with current and former fire mechanics, review of safety data sheets (SDSs) for chemical products used by the fire mechanics and compilation of relevant toxicity data to determine which chemical substances are considered carcinogens and the availability of criteria to quantitatively evaluate the potential cancer risk from exposure to the substances.

Through email correspondence with the American Federation of State, County & Municipal Employees (AFSCME) Local 119 representatives, ToxStrategies identified the County of Los Angeles Fire Department mechanic classifications and three main sites of operation. The fire mechanic classifications (SEGs) are (1) Equipment Maintenance Worker, (2) Fire Equipment Mechanic (FEM), (3) Helicopter Mechanic, and (4) Helicopter Maintenance Inspector. We also recognized a category of Field Mechanics, who work across the county at local fire stations and at locations where fire equipment is dispatched, including wildfires. These mechanics do not work at the main facilities but have similar potential for exposure, because they contact the residue from fires that is on the surface of the equipment.

ToxStrategies conducted site visits at the three main sites of operation, which included:

- Eastern Fire Shop, located at 1104 N Eastern Avenue, Los Angeles, 90063
- North County Fire Shop, located at 42110 6<sup>th</sup> Street West, Lancaster, 93534
- Pacoima Air Operations & Breathing Apparatus (BA) Shop, located at 12605
   Osborne Street, Pacoima 91331.

During the visits, ToxStrategies conducted 12 in-person interviews with current LA County fire mechanics and fire mechanic supervisors. We met with mechanics from all job classifications at all three locations to discuss their work activities and potential exposures. Three virtual interviews were conducted with current and former LA County fire mechanics and one virtual interview was conducted with a fire mechanic from the Menlo

Park Fire Protection District in Northern California. Continued correspondence/data-gathering occurred throughout the study period with AFSCME representatives.

The purpose of the site visits (walk-around surveys) and personnel interviews (in-person and conference calls that occurred after the in-person site visits) was to gather information regarding chemical exposures of fire mechanics by recording observations of potential sources of exposures to chemical carcinogens at each location, as well as the manner in which these exposures may occur. The survey approach included identifying chemical agents in the workplace and discussing the overall job and specific work tasks conducted by each of the fire mechanic classifications. The survey goals were to understand how and when workers are exposed to the chemical agents, ascertain information regarding the availability and use of exposure controls (personal protective equipment [PPE], engineering/administrative controls, work practice controls), and discuss the evolution of chemical usage and work practices over time.

ToxStrategies reviewed SDSs used at the Eastern Fire Shop and the North County Fire Shop. However, SDSs for products used at the Pacoima Air Operations and the Breathing Apparatus Shop were not available; therefore, chemical usage information was obtained through the site visits and personnel interviews only.

The risk ranking matrix (Figure 2 above) was used to identify and prioritize high-risk chemical exposures, which allowed ToxStrategies to target the DIR resources for Task 4 and focus on potential exposures with the highest potential chemical exposures to carcinogens.

Some specific concerns identified by the fire mechanics, that were also prioritized as highrisk chemical exposures, included:

- Diesel exhaust at the Eastern and North County Fire Shops
- Smoke and fire residue exposures at a wildfire base camp
- Fire residues on the underside and inside the mechanical compartments of the fire truck, including fire equipment (e.g., fire hoses)
- Hexavalent chromium residue on aircraft engines and other aircraft parts at Air Operations
- Fire residues on the aircraft at Air Operations
- Jet A fuel exhaust in the hangar at Air Operations
- Fire residues on the breathing apparatus and fire hoses at the Breathing Apparatus Shop.

Further, ToxStrategies identified strong gasoline odors when entering the small engine repair shop at the Breathing Apparatus Shop during one of the site visits. Therefore, this area was prioritized for the quantitative exposure assessment (Task 4).

Job titles, locations, tasks and associated chemicals and qualitative exposure ranking are presented in Table 2. The chemicals identified in Task 2 were reviewed and updated prior

to collecting and analyzing samples in Task 4. Table 2 below shows the updated list as included in Task 4.

Table 2. Job titles, tasks, and relevant chemical carcinogens identified for quantitative analysis

The Task 2 report is attached as Appendix B.

#### 4 Epidemiology Feasibility Study (Task 3)

The objective of Task 3 was to determine the feasibility of conducting an epidemiologic evaluation of risk of cancer in fire mechanics. ToxStrategies staff interviewed LA County fire equipment mechanics and a representative from LA County Fire human resources (HR) to determine the availability of information needed to conduct an epidemiologic study. The feasibility study consisted of four steps:

- Exposure verification (identify fire mechanics). Employees considered to be fire mechanics could be selected using a list of specific job classification codes obtained during a ToxStrategies site visit. Fire mechanics could be identified using these codes through LA County personnel records, which date back to 1975.
- Outcome ascertainment (track fire mechanics for cancer). Fire mechanics could be tracked for incidence cancer diagnoses using the California Cancer Registry, from 1988 forward (1972 forward if diagnosed in LA County), or for death due to cancer using the National Death Index, from 1979 forward. Employees could be linked to these registries using their social security number and/or date of birth, both of which are available in personnel records.
- Cohort enumeration (determine size of cohort). Using two systems of personnel records, LA County Fire HR determined there were 180 individual employees considered to be fire mechanics from September 1975 to January 2021.
- Confounding variables (evaluate characteristics that may confound the
  relationship between occupation and cancer). Fire mechanics complete a preemployment physical at an occupational health clinic, where records of
  smoking history, alcohol consumption, and medical history are likely available.
  These records would need to be obtained from the occupational health clinic
  directly. Some variables may also be available in the registries.

While it would be feasible to assemble a cohort of fire mechanics in LA County and track participants' cancer diagnoses, the number of employees within this potential cohort would

not likely be large enough to detect any significant increased risk of cancer. If the cancer risk in fire mechanics was similar to that of firefighters, approximately 1,000 fire mechanics, with an average of 10 years of follow-up each, would be necessary to detect a statistically significant increased risk of cancer. Evaluating the potential of expanding the cohort to fire mechanics throughout the State of California is recommended as a future activity.

The Task 3 report is attached as Appendix C.

#### **5** Quantitative Exposure Assessment (Task 4)

The purpose of Task 4, Quantitative Exposure Assessment, was to conduct exposure monitoring of workers for airborne chemicals, as well as chemical analysis of surface residues, based on the findings from Tasks 1 and 2. Samples from each SEG were selected for PBZ air sampling and surface wipe sampling of equipment.

The chemical carcinogens identified during the literature review task (Task 1; Section 2 above) and selected for PBZ air sampling and/or surface wipe sampling were benzene, diesel exhaust, PAHs, crystalline silica, ethylbenzene, PCBs, acetaldehyde, formaldehyde, styrene, and chlorinated dioxins/furans.

The job tasks that were identified during the qualitative exposure assessment (Task 2; Section 3 above) as ranking moderate, high, and very high were selected for PBZ air sampling and/or surface wipe sampling. Further, ToxStrategies quantitatively assessed each of the fire mechanics' concerns listed in Section 3 above, with the exception of the smoke and fire residue exposures at a wildfire base camp since there were no active fires during the month of our sampling events and spray painting of aircraft because that activity is infrequent and not scheduled for the days of the assessment.

ToxStrategies collected PBZ air samples and surface wipe samples on November 3, 2020 at Air Operations (Pacoima) and the Breathing Apparatus Shop (Pacoima), and November 4, 2020 at the Eastern Fire Shop (Los Angeles). Please note that ToxStrategies did not conduct quantitative sampling at the North County Fire Shop (Lancaster) because fire equipment mechanics perform similar job tasks at both sites, and the North County Fire Shop is a much smaller facility than the Eastern Fire Shop. Therefore, the results obtained at the Eastern Fire Shop were assumed to be representative of the North County Fire Shop. To stay within the constraints of the budget and schedule and to minimize potential exposures between sampling personnel and fire mechanics in light of the COVID-19 in the fall 2020, sampling was conducted on one day at each of the locations.

Sampling was conducted with a focus on the highest exposure opportunities. For example, a fire engine was running inside the Eastern Fire Shop adjacent to where an area PBZ air sample was being collected; PBZ air samples were collected where gasoline odors were observed at the small engine repair shop (at the Breathing Apparatus Shop); surfaces were sampled where the highest amount of residue was observed; and surfaces were sampled on aircraft and fire trucks that had recently been in a wildfire.

Table 3 provides an overview of the PBZ sampling and analyses, and Table 4 provides an overview of the surface wipe samples and analyses. The quantitative exposure results from Task 4 were used subsequently in the cancer risk assessment (Task 5). In addition, four bulk samples of vermiculite-coated fiberglass strips used to wrap the fire apparatus exhaust were collected and analyzed for asbestos. Asbestos was not detected in any samples.

#### Notes:

- 1. Ratio indicates number of detections over total number of samples analyzed.
- 2. Each PBZ sample represents an 8-hour time-weighted average.
- 3. Diesel particulates measured as elemental carbon
- 4. Only carcinogenic welding fume chemicals are presented.
- 5. Chemicals not detected in any samples.
- 6. "—" indicates samples were not analyzed for this chemical.

#### Abbreviations:

Cr(VI) – hexavalent chromium, PCE – tetrachloroethylene.

#### Notes:

- 1. Ratio indicates number of detections over total number of samples analyzed.
- 2. "—" indicates samples were not analyzed for this chemical.
- 3. PAHs were only detected on training air packs.

#### Abbreviations:

PAHs – polycyclic aromatic hydrocarbons (16 chemicals including naphthalene), Cr(VI) – hexavalent chromium, PCBs – polychlorinated biphenyls (162 congeners or congener groups), Dioxins/Furans – chlorinated dioxins and furans (17 congeners,) and PCP – pentachlorophenol

The Task 4 report is attached as Appendix D.

#### 6 Cancer Risk Assessment (Task 5)

The Task 5 report provides a quantitative health risk assessment of potential increased cancer risk associated with exposure to carcinogens in the workplace. This risk assessment was prepared based on regulatory guidance used in the State of California for the purpose of assessing exposure and risk. Site-specific information gathered as part of Task 2,

qualitative exposure assessment, was used to refine the exposure assumptions used in the risk assessment calculations.

The cancer risk assessment is an estimate of the theoretical increased risk of developing cancer as a result of exposure to chemicals present in the workplace. This approach involves varying degrees of conservatism and ensures that cancer risk is not underestimated, which makes it probable that the estimated risk will be overestimated. It is important to consider that these risks are theoretical because they are not measured directly among fire mechanics, which could only be done through use of an epidemiology study (as discussed in Task 3).

Consistent with regulatory guidance, the risk assessment was performed in a series of four steps:

#### Hazard Identification

During Task 4 quantitative exposure assessment, ToxStrategies conducted exposure monitoring of workers in each similar SEG for airborne chemicals, via PBZ air samples, as well as chemical analysis of surface residues via surface wipe samples. Samples were not collected for the field-assigned fire equipment mechanic at a wildfire base camp or for the helicopter maintenance inspector conducting painting/priming/sanding of aircraft parts because those activities were not on-going when sampling was performed.

Acetaldehyde, benzene, cobalt, formaldehyde, hexavalent chromium, nickel, and tetrachloroethylene were detected in at least one PBZ air sample. Hexavalent chromium, lead, PAHs, PCBs, and dioxins/furans were detected in at least one surface wipe sample. These chemicals were all considered to potentially increase the risk of cancer and were quantitatively evaluated in the risk assessment.

#### Exposure Assessment

In Task 2 qualitative exposure assessment, ToxStrategies provided an exposure ranking for each SEG exposed to carcinogens identified in the workplace in order to focus the Task 4 quantitative exposure assessment to those exposures (job tasks) that may pose the highest risk. Three primary scenarios were evaluated quantitatively in the risk assessment.

- Helicopter mechanic performing intermediate and heavy maintenance on the aircraft at Air Operations;
- Equipment maintenance worker performing repair and tune-up of power equipment at the small engine repair shop (Breathing Apparatus Shop); and
- FEM performing maintenance and repair of the fire apparatus at the Eastern Fire Shop.

Four additional SEGs, based on specific activities or contact with potentially contaminated materials were also included:

• Mastinox contact by the helicopter mechanic at Air Operations;

- Welding/grinding/cutting activities by the FEM at the Eastern Fire Shop;
- Repair and tune-up of the air packs at the Breathing Apparatus Shop; and
- Fire hose repair by the equipment maintenance worker at the fire hose repair shop (Breathing Apparatus Shop).

Exposure assumptions from regulatory guidance or based on site-specific information obtained during interviews during Task 2 were assigned to each SEG for the purpose of evaluating inhalation, dermal contact, and incidental ingestion exposures. Concentrations at the point of exposure were developed from the Task 4 data using averages when multiple samples were collected and maximum values when a few samples were collected. If an analyte was not detected in any samples at a location, it was not considered further in the risk assessment.

The air concentrations in each of these locations were below Permissible Exposure Limits (PELs), legal limits below which workers are allowed to be exposed; however, PELs are not always established to be protective of an increased cancer risk.

#### Toxicity Assessment

Toxicity criteria quantifying the relationship between chemical exposure and theoretical increased cancer risk were identified from regulatory references. Preference was given to criteria developed by a California regulatory agency or health agency. Other chemical-specific factors such as an adjustment to toxicity criteria based on ingestion exposures were made to quantify risk from dermal exposure. Some chemicals did not have regulatory toxicity criteria and were evaluated qualitatively.

#### Risk Characterization

Risk characterization is the integration of the exposure assessment and toxicity assessment to provide a quantitative estimate of theoretical risk. For the purpose of this risk assessment, excess cancer risks calculated to be less than 1 in 10,000 (recently adopted by the NIOSH) were considered *de minimus*.

Exposure via dermal contact and incidental ingestion exposure were much lower than inhalation exposure for all SEGs, and lower than the target criteria set by NIOSH. Theoretical excess cancer risks ranged from 0.0009 in 10,000 for fire hose repair to 0.2 in 10,000 for contact with Mastinox.

Based on the risk assessment process described herein, theoretical risks for inhalation exposure for the primary SEGs were as follows, with the primary chemical noted in the parentheses:

- 20 in 10,000 (0.2%) at Air Operations (hexavalent chromium)
- 30 in 10,000 (0.3%) at the Breathing Apparatus Shop, specifically measured at the small engine repair shop (benzene)
- 400 in 10,000 (4%) at the Eastern Fire Shop (tetrachloroethylene).

It is noteworthy that these risk estimates are based on current sampling data and may not be reflective of past exposures; however the assessment assumes that exposure occurs for a working lifetime of 45 years. As worker safety and health practices typically improve with time, it is reasonable to assume that exposures in the past may have been higher and different than those quantified herein.

In any risk assessment, estimates of potential carcinogenic risk are based on assumptions regarding exposure and toxicity, which have numerous associated uncertainties. Where possible, conservative assumptions were used to address uncertainty such that risks associated with the chemical exposures evaluated in this study are expected to be overestimated.

It is also noteworthy that while the theoretical increased cancer risks calculated for inhalation exposures exceed the current NIOSH benchmark of 1 in 10,000, these risks are far lower than that measured among firefighters. Increased cancer risks among firefighters have been documented in epidemiological studies. The IARC Working Group's analysis of firefighters found that the risk of testicular cancer was increased by  $\sim$ 50%, the risk of prostate cancer by  $\sim$ 30% and the risk of non-Hodgkin's lymphoma by  $\sim$ 20%². As discussed in Task 1, similar studies of fire mechanics have not been performed, but the feasibility of such was assessed in Task 3 of this project.

To reduce theoretical cancer risk for the exposures identified above, a variety of control measures consistent with the NIOSH hierarchy of controls (eliminate, substitution, engineering controls, administrative controls, and use of PPE) could be considered. Examples include:

- Eliminate tetrachloroethylene-containing products, replacing them with products that do not contain carcinogens.
- Increase ventilation in the small engine repair shop to reduce benzene air concentrations.
- Identify work practices at Air Operations that increase the potential for airborne hexavalent chromium releases, and modify practices/procedures to reduce the release.

The Task 5 report is attached as Appendix E.

#### 7 Technical Assistance to the DIR (Task 6)

Task 6 may include analyzing public comments, explaining the rationale for specific policy recommendations, and disseminating the study findings to the Governor, Legislature,

#### 1 Background and Rationale

The International Agency for Research on Cancer (IARC) and recent epidemiologic studies have suggested that firefighters may be at increased risk for certain cancers due to their occupational exposures to carcinogens found in fire gases and smoke (e.g., benzene, polycyclic aromatic hydrocarbons [PAHs], cadmium, crystalline silica [IARC, 2010]) as well as exposures to other agents (e.g., diesel exhaust [IARC, 2010]) (e.g., IARC, 2010; Tsai et al., 2015; LeMasters et al., 2006). Since January 1, 2012, firefighters have been included in the California Cancer Presumption for worker compensation purposes (California Labor Code §3212.1). With these benefits, a firefighter who develops cancer can be awarded compensation for medical treatment and disability benefits, if the individual demonstrates that he or she was exposed to a carcinogen during the course of their employment. In comparison, mechanics who repair and clean firefighting vehicles and equipment are not covered by this worker compensation program. Repairing and cleaning firefighting vehicles and equipment (trucks, helicopters, axes, hoses, etc.) at a fire station or offsite at a fire event may expose the mechanics to fire-related carcinogens, similar to those of the firefighters. However, chemical data for fire mechanics are not readily available, and their occupational exposures are not well characterized, limiting the evaluation of their potential cancer risks.

As a result, California Assembly Bill (AB) 1400 was created to define the fire mechanic's risk of exposures to carcinogens in the course of employment. Specifically, AB 1400, Section 77.7, was added to the Labor Code on October 11, 2019, and requires the Commission on Health and Safety and Workers' Compensation (CHSWC), in partnership with the County of Los Angeles and relevant labor organizations, to submit a study to the Legislature, the Occupational Safety and Health Standards Board, and the Los Angeles County Board of Supervisors "on the risk of exposure to carcinogenic materials and incidence<sup>2</sup> of occupational cancer in mechanics who repair and clean firefighting vehicles." The study components include:

- Site visits at representative facilities in Los Angeles County, California
- Interviews and surveys with current and former fire mechanics

\_

California Legislative Information. 2019. AB-1400 Employment safety: Firefighting equipment: Mechanics (2019–2020). Bill Analysis. Senate Committee on Labor, Public Employment and Retirement. Hearing Date: July 10, 2019.

As discussed in Section 6, insufficient information currently exists to assess the incidence rate of cancer among firefighting mechanics. For this project, we will evaluate the available information and assess the feasibility of generating the data that could potentially be used in a future epidemiologic study.

California Legislative Information, 2019. AB-1400 Employment safety: Firefighting equipment: Mechanics (2019-2020). Assembly Bill No. 1400, Chapter 717, An act to add and repeal Section 77.7 of the Labor Code, relating to employee safety. October 11. <a href="https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill\_id=201920200AB1400.">https://leginfo.legislature.ca.gov/faces/billTextClient.xhtml?bill\_id=201920200AB1400.</a>

- Occupational exposure measurements of carcinogens found in the workplace, to evaluate potential exposure to carcinogenic materials
- Quantitative health risk assessment of potential increased cancer risk associated with exposure to carcinogens in the workplace.

ToxStrategies was contracted by the California Department of Industrial Relations (DIR), CHSWC, to conduct the study as outlined in AB 1400. ToxStrategies' approach to address these study components includes six tasks (provided in our proposal submitted to the DIR [ToxStrategies, Inc., 2020]):

- Task 1: Structured Literature Review—provided herein
- Task 2: Qualitative Exposure Assessment site visits at representative facilities
- Task 3: Epidemiologic assessment feasibility study of cohort enumeration
- Task 4: Quantitative Exposure Assessment measurement of current occupational exposures to carcinogens
- Task 5: Cancer risk assessment calculation of theoretical excess cancer risks from occupational exposure to carcinogens
- Task 6: Technical assistance to the DIR.

The purpose of Task 1, Structured Literature Review, is to identify and review relevant published literature to understand the state of the science with respect to exposure to chemical carcinogens associated with repairing and cleaning firefighting vehicles and equipment, as well as studies of cancer risk among fire mechanics.

The objectives, methods, results, and conclusions of Task 1, Structured Literature Review, are provided below. The remaining study tasks are described in Section 6.

#### 2 Objectives

The objectives of this structured literature review were as follows:

- 1. Identify carcinogenic chemicals of potential concern (COPCs) for mechanics who repair and clean firefighting vehicles and equipment
- 2. Identify epidemiologic studies evaluating the risk of cancer among mechanics who repair and clean firefighting vehicles and equipment.

The structured literature review results will be used to guide the activities of the latter tasks.

#### 3 Methods

Standard guidelines to conduct structured literature reviews, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, were followed in the conduct of this review (Moher et al., 2009). A protocol was developed *a priori* before the review was conducted to ensure clear documentation of methods and for transparency and reproducibility of our work (Attachment 1).

#### 3.1 Study Eligibility

The inclusion and exclusion criteria used to assess study eligibility are presented in Tables 1 and 2 for Objectives 1 and 2, respectively. English-language articles published as either peer-reviewed journal articles or conference abstracts through the date of the search (August 15, 2020), with no lower date limit, were included in the review.

Table 1. Study eligibility criteria for Objective 1: Identify carcinogenic chemicals of potential concern for mechanics who repair and clean firefighting vehicles and equipment.

|              | Inclusion Criteria                                                                                                                     | Exclusion Criteria                                                                           |

| Exposure             | Occupational exposures to potential chemical carcinogens                                                                               | Non-occupational exposures to chemical carcinogens |  |
| Comparator           | General population, non-exposed worker populations (e.g., office workers within firefighting discipline), workers with lower exposures | No control group                                   |  |
| Outcome Cancer (any) |                                                                                                                                        | Non-cancer outcomes                                |  |
| Study Design         | Cohort, case-control, case studies or case series                                                                                      | Opinion pieces, reviews                            |  |

The bibliographies of relevant reviews and publications were hand-searched for additional citations of interest.

#### 3.2 Initial Literature Search

We conducted a primary literature search on June 30, 2020, in the PubMed and Embase databases to 1) identify studies on occupational exposures of mechanics who repair and clean firefighting vehicles and equipment to carcinogenic chemicals of potential concern (COPCs) and 2) identify epidemiologic studies evaluating the risk of cancer among mechanics who repair and clean firefighting vehicles and equipment, using the search syntax presented in Table 3.

Table 3. Initial search syntax used for PubMed and Embase

| Database | Search Syntax                                                                                                                                                                                                                                                                                                                           |

#### 3.3 Initial Search Study Selection

Study selection was documented through DistillerSR, a specialized software program designed for tracking and managing literature reviews, resulting in a fully auditable and transparent review process. A PRISMA flow diagram is included in the results section, detailing the flow of study inclusion and exclusion at each study level.

The review of studies began at the level of title and abstract. Two reviewers screened the titles and abstracts of all de-duplicated studies resulting from the literature searches to determine their relevance for this review using the eligibility criteria (Tables 1 and 2).

Articles designated as relevant from the title and abstract review proceeded to full-text review, where two reviewers independently evaluated the full text of each article for relevance using the eligibility criteria (100% quality control [QC]). All disputes regarding study inclusion were resolved by consensus adjudication. The results were recorded, maintained, and assessed using DistillerSR.

#### 3.4 Initial Search Data Abstraction

Data were abstracted in DistillerSR for all studies deemed relevant to the review by both reviewers in the full-text review stage.

Data abstraction elements were as follows:

- **General information**, including title, authors, and year of publication
- Study characteristics:
  - By person (demographics, job, confounders)
  - By place (geography, workplace/facility)
  - By time (calendar years of conducted study and follow-up)

#### Outcomes

- **Objective 1: Occupational exposures** (chemical, exposure levels)
- Objective 2: Cancer-related outcomes (numbers, incidence rate, mortality rate, odds ratios, risk ratios, hazard ratios, standardized incidence ratios, standardized mortality ratios).

#### 3.5 Supplemental Literature Search for Cancer Outcomes

To ensure that relevant occupational studies were not missed using the original search strings (Table 3), supplemental targeted literature searching was conducted. If the cancer outcomes were not statistically significantly associated with fire mechanics, they may not be captured in the abstract or keywords of the indexed publications and thus would not have been picked up by the original searches. Given the specificity of the fire mechanics occupation and previously established lack of research for these workers, we conducted

additional searches to identify relevant literature that may not have been picked up by our original searches.

First, we reviewed the International Agency for Research on Cancer (IARC) monographs (2010) to identify cancers potentially associated with firefighting as an occupation. IARC is the World Health Organization agency that conducts and coordinates research into cancer. IARC working groups regularly review the carcinogenicity of chemicals and occupations using the available scientific literature and release monographs rating the carcinogenicity of the exposure based on the panel's scientific judgment. IARC published a monograph reviewing the carcinogenicity of firefighting in 2010 which included a list of cancers potentially associated with firefighting as an occupation (Non-Hodgkin's lymphoma, prostate cancer, and testicular cancer). Using this list of cancers, we expanded our PubMed and Embase search to identify epidemiologic studies of associations between these particular cancers and occupational groups to identify potentially missed research on cancer risk among fire mechanics (Table 4, cancer cohorts search).

Second, because there is no published IARC monograph for mechanics (automotive or other), and to provide additional context for potential cancers in the fire mechanic population, we conducted a targeted search in PubMed and Embase for epidemiologic studies of automotive mechanics and cancer (Table 4, mechanics and cancer search).

Finally, because Nordic registry-based cohort studies are known to provide robust analyses of cancer by occupation and are known to have high validity and statistical power due to large population size and complete follow-up, published literature from these cohorts was searched for fire mechanics or related occupations. Specifically, we reviewed data from Nordic cohort studies for elevated cancer risk among general mechanics, automotive mechanics, and fire mechanics (Table 4, Nordic cohorts search).

Table 4. Supplemental search syntax for PubMed

#### 3.6 Supplemental Study Data Abstraction

Studies identified during our supplemental searches (as described in Section 3.5) were reviewed for relevance at the title and abstract level; relevant full-text studies were searched for data for fire mechanics. Due to the volume of studies found in the cancer cohorts search (over 1,500), we used the Sciome Workbench for Interactive computer-Facilitated Text-mining (SWIFT-Review) interactive text-mining tool to further narrow these results by scanning titles, abstracts, keywords, MeSH annotations, and SWIFT-generated tags for the following syntax: "occupational AND cohort AND cancer AND occupations," "fire AND (maintenance OR cleaning OR mechanic)," and "mechanic AND cohort."

Relevant studies from the supplemental search were summarized and cited within the report but were not included in the data abstraction table, because while they provided contextual information that will help inform future work, they did not provide data that is specific to fire mechanics.

#### 4 Results

The initial database search yielded 341 publications, and hand-searching of reviews and studies included for abstraction yielded another four. After de-duplication and screening of titles and abstracts, 20 papers were deemed relevant for full-text review. Upon full-text review, nine studies were found to be relevant for abstraction of exposure data, as shown in the PRISMA flow diagram (Figure 1).

This review was limited to peer-reviewed journal articles and conference abstracts published in English. Information published in the grey literature was excluded. The results of this review are generalizable only to the geographic areas and populations included in the studies.

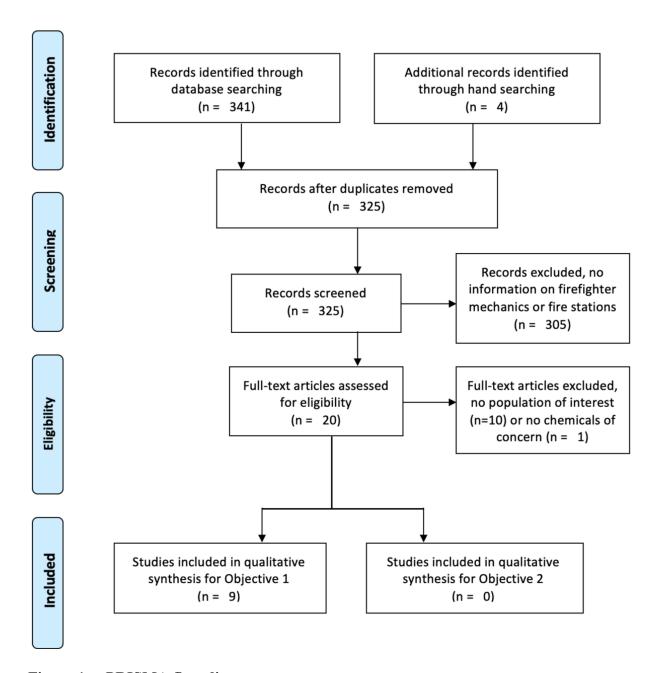

Figure 1. PRISMA flow diagram

### 4.1 Objective 1: Chemicals of Potential Concern (COPCs) for Fire Mechanics

The literature was extremely limited regarding exposures of mechanics who repair and clean firefighting vehicles and equipment (e.g., trucks, axes, hoses, etc.). No exposure studies explicitly mentioned fire mechanics, fire mechanic cleaners, or fire vehicle maintenance. However, we were able to identify nine industrial hygiene studies that presented data for exposures relating to fire stations and firefighting vehicles and/or gear, which likely overlap with exposures that fire mechanics encounter (Chung et al., 2020; Echt et al., 1995; Fent et al., 2015; Froines et al., 1987; Materna et al., 1992; Park et al., 2015; Shen et al., 2015; Shen et al., 2012; Sparer et al., 2017). The industrial hygiene studies are summarized in Table 5, including exposure findings related only to COPCs that are carcinogenic<sup>4</sup>; full study details for the nine included papers are included as Attachment 2 (Data Abstraction File). Whether a COPC was classified as a carcinogen was determined using Cal/OSHA's Hazard Communication Standard, which compiles listings from the following sources:<sup>5</sup>

- National Toxicology Program (NTP), "Report on Carcinogens" (NTP, 2016)
- International Agency for Research on Cancer (IARC) "Monographs on the Evaluation of Carcinogenic Risks to Humans" (IARC, 2020)
- Substances subject to regulation under the Occupational Carcinogen Control Act or that are regulated in Title 8, Article 110, Regulated Carcinogens (§5209, Carcinogens)
- Substances that meet the definition of "select carcinogen" in Title 8, Section 5191
- Where OSHA has included cancer as a health hazard to be considered by classifiers for a chemical covered by 29 CFR part 1910, Subpart Z.

\_

A carcinogen is defined as "a substance or mixture of substances which induce cancer or increase its incidence" (Appendix A to §1910.1200 – Health Hazard Criteria).

Five studies were conducted in California:

- Three studies used data collected from the Firefighter Occupational Exposures (FOX) study (Park et al., 2015; Shen et al., 2015; Shen et al., 2012) which measured polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and organochlorine pesticides (OCPs)
- One study conducted industrial hygiene sampling (crystalline silica, acetaldehyde, formaldehyde, PAHs, and benzene) among firefighters working at northern California wildland fires between 1987 and 1989 (Materna et al., 1992)
- One study measured total particulates as diesel emissions at three fire stations, one of which was in southern California (Los Angeles; discussed below) (Froines et al., 1987).

The FOX study (Shen et al., 2015, 2012) collected surface dust samples from fire stations in California between 2010 and 2011, and the authors reported the level of PAHs in fire stations as being higher than those found in California homes, and the level of PCBs as similar to California homes. In addition to surface dust samples, the FOX study also measured levels of PCBs and OCPs in firefighter serum; the study authors reported that firefighting is not a significant source of exposure to PCBs and OCPs (Park et al., 2015).

The firefighter industrial hygiene samples collected during wildland firefighting demonstrated potential for low-level exposures to carcinogens such as crystalline silica, acetaldehyde, formaldehyde, PAHs, and benzene (Materna et al., 1992).

Four studies investigated diesel emissions in fire stations:

- Froines et al. reported that fire vehicles were the major contributor of total particulates from diesel emissions after measuring exposures in ten fire stations in New York, Boston, and Los Angeles (1987). Further, firefighter exposure to total particulates increased with the number of runs conducted during an 8-hour period.
- Echt et al. found that the highest levels of elemental carbon (as a proxy for diesel exhaust) were measured in the fire station vehicle bays (maximum area sample measured up to  $683 \mu g/m^3$  of elemental carbon), which can travel to other areas of the fire station, such as the living quarters (1995).
- Sparer et al. found levels of particulate matter (PM<sub>2.5</sub>; proxy for diesel exhaust) and PAHs in fire station truck bays to be higher than the outside measurements, although the authors acknowledged that tobacco smoke was a confounding factor on some days (2017).
- Chung et al. reported that the majority of respirable elemental carbon concentrations (proxy for diesel engine exhaust) came from the vehicle bays; higher concentrations were observed in the summer, potentially due to higher activity levels (2020).

Finally, Fent et al. (2015) measured off-gassing from firefighters' personal protective equipment (PPE) after being exposed to a controlled burn. The study results showed that the air concentrations of benzene, 1,4-dichlorobenzene, ethylbenzene, and styrene measured from the used PPE were higher than the measured background levels. Interestingly, brand new PPE had a higher measured off-gassing air concentration of 1,4-dichlorobenzene than that of the used PPE that had been exposed to a controlled burn.

The identified carcinogens in the exposure studies above are described in more detail below (Table 6). Each of the carcinogens is presented, along with the target cancer endpoint, and the carcinogen-identifying authoritative body (IARC, 2020; NTP, 2016; 29 CFR part 1910, Subpart Z [OSHA]). The evidence for chemical classification is based on a variety of animal and/or human studies and is not specific to observations among fire mechanics.

Table 6. Carcinogenic chemicals of potential concern (COPCs) identified in the literature review

| Carcinogen Identified in Exposure Studies | Target Cancer Endpoints<br>(IARC, 2020; NTP, 2016)                                                                                                                                                                                      | Identifying Authoritative<br>Body |

#### 4.2 Objective 2: Epidemiologic Studies of Cancer Among Fire Mechanics

#### 4.2.1 Initial Literature Search

The initial literature search did not identify any studies reporting on cancer risk, or rates of prevalent or incident cancers among fire mechanics. It is possible that the lack of findings is due to publication bias (i.e., groups without elevated or statistically significant results are less likely to be reported); thus to further ensure that relevant data were not missed, we conducted supplemental searches for related occupations (firefighters and auto mechanics) and compiled information from other sources for firefighters to further search for information specific to fire mechanics.

#### 4.2.2 Supplemental Literature Search for Cancer Outcomes

The supplemental search for specific cancer types and occupational cohorts yielded over 1,500 references in PubMed and Embase (cancer cohorts query, Table 4); however, text mining in SWIFT-Review, as described in section 3.6, for related studies did not indicate that any studies included data for fire mechanics. While we acknowledge that there is still a small chance that this population has been mentioned in passing in a study with another focus, which would not be indexed in any searchable capacity, our supplemental searching and review of studies of related populations did not reveal any findings to support that relevant data had been missed with our original search strategy. In short, no studies quantifying cancer risk specifically among fire mechanics were identified even through the supplemental search strategy.

After conducting a meta-analysis of 42 studies of cancer in firefighters (19 cohorts, 11 case-control studies, and 14 "other" studies), the IARC Working Group reported that only testicular cancer, prostate cancer, and non-Hodgkin's lymphoma showed significant summary risk estimates (2010). The Working Group identified indirect measurements of exposure (e.g., duration of employment) as a limitation of existing studies (IARC, 2010). Based on their review, the overall evaluation of occupational exposure as a firefighter was

possibly carcinogenic to humans (2B), based on limited evidence in humans and inadequate evidence in experimental animals (IARC, 2010).

A systematic review of the literature of cancer risks associated with occupations in firefighting and motor vehicle maintenance and repair is necessary to thoroughly characterize the risk of cancer in these populations. Our preliminary review of the secondary literature for epidemiologic studies of automotive mechanics and cancer suggests occupational exposure may be associated with an increased risk for bladder cancer, and is likely not associated with lung cancer or leukemia (Muscat et al., 1995; Reulen et al., 2008).

Finally, our review of the Nordic cohort studies for general mechanics, automotive mechanics, and fire mechanics, showed statistically significant associations between mechanics<sup>6</sup> and several specific cancer types (e.g., bladder, cervix, colon, esophageal, etc.; Pukkala et al., 2009). However, it is worth noting that the definition of mechanics used in these studies was not specific to automotive mechanics and may include other occupations, and therefore the Pukkala et al. cancer types were not included in Table 7 (2009). Prior to that report, smaller Nordic studies of cohorts of automotive mechanics and bus garage workers showed elevated risks of non-Hodgkin's lymphoma, pancreatic cancer, urinary cancer outside the bladder (ureter and urethra), pleural mesothelioma, and lung cancer (Dryver et al., 2004; Hansen, 1989; Gustavsson et al., 1990). However, no results were found for fire mechanics in these studies, and the exposures and risks of all mechanics combined may not be generalizable to fire mechanics or automotive mechanics.

The various cancer sites and types reported in the primary literature for automotive mechanics and in the Nordic cohort studies specific to automotive mechanics are presented in Table 7. The cancer types associated with firefighters (as identified by the meta-analysis presented in IARC, 2010) are provided for additional context as to potential cancers that may have overlap with fire mechanics.

\_

<sup>&</sup>quot;Mechanics" was defined as "workers who make products of metal, and assemble and repair machines and motors" (Pukkala, et al., 2009).

Table 7. Reported cancer types potentially associated with occupation in firefighting and automotive maintenance and repair

| Cancer Site or Type    | Secondary<br>Literature,<br>Auto Mechanics | Nordic Cohorts,<br>Auto Mechanics | IARC, Firefighters |
|------------------------|--------------------------------------------|-----------------------------------|--------------------|
| Bladder                | X                                          |                                   |                    |
| Lung                   |                                            | X                                 |                    |
| Mesothelioma           |                                            | X                                 |                    |
| Non-Hodgkin's Lymphoma |                                            | X                                 | X                  |
| Pancreas               |                                            | X                                 |                    |

#### 5 Discussion and Conclusions

This structured literature review illuminated the paucity of literature available for the characterization of potential carcinogenic exposures and cancer risks of fire mechanics. Occupation as a fire mechanic and risk of cancer has not been evaluated in the current scientific literature.

For the first objective of identifying studies reporting carcinogenic exposures experienced by fire mechanics, no occupational chemical exposure studies explicitly focused on fire mechanics, fire mechanic cleaners, or firefighting vehicle maintenance workers. However, nine industrial hygiene studies presented data for fire stations and firefighting vehicles and/or gear, which likely overlap with the occupational exposures of fire mechanics who repair and clean firefighting vehicles. The chemical carcinogens evaluated in these studies included benzene, diesel exhaust, PAHs, PCBs, OCPs, acetaldehyde, formaldehyde, crystalline silica, 1,4-dichlorobenzene, ethylbenzene, and styrene.

For the second objective of identifying studies of cancer risks or rates among fire mechanics, no epidemiologic studies were identified. A supplemental search was conducted to identify risk of cancer in the related occupations of firefighting and automotive maintenance and repair. Though a more thorough systematic review is necessary to fully characterize the risks in these occupations, our preliminary review of IARC monographs and the supplemental literature demonstrated that a number of cancers have been reported as increased in both firefighters and general or automotive mechanics. While the studies of firefighters and automotive mechanics provide additional insight into the risks associated with these related occupations, the results of these studies may not be generalizable to the experience of fire mechanics.

The findings from this literature are informative with respect to potential chemical exposures to be evaluated in the qualitative and quantitative exposure assessments that ToxStrategies will conduct (i.e., Tasks 2 and 4).

#### 6 Next Steps

During the initial site visits, ToxStrategies will conduct a qualitative exposure assessment (Task 2) to determine similar exposure groups (SEGs) among the workers and prioritize/define the scope of the quantitative exposure assessment based on a risk ranking that incorporates the relative magnitude of the exposure potential (AIHA, 2015). A walk-around survey of the selected fire stations will be conducted, and observations will be made of the potential sources of exposures to chemical carcinogens at each location, as well as the manner in which those exposure may occur to characterize the exposures to fire mechanics who repair and clean firefighting vehicles.

Based on the findings from the literature and facilities records review (Tasks 1 and 2), employee records will be evaluated for completeness and suitability for a future cancer epidemiologic study (Task 3). As identified in the proposed scope of work submitted by ToxStrategies, due to the study timeline and scope, it is not feasible to calculate cancer incidence in this study population of fire mechanics. Interviews with current and former fire mechanics will provide observational information of cancer cases, but this information is not sufficient to demonstrate associations with chemical exposure, nor a causal relationship with the jobs of fire mechanic or firefighting vehicle cleaner.

The scope of the quantitative assessment (Task 4) will be determined from the results of the qualitative assessment, but we anticipate that exposure monitoring of workers for airborne chemicals, as well as chemical analysis of surface residues, will be included. SEGs will be assigned, and a representative number from each group will be selected for personal breathing-zone (PBZ) air sampling and surface/dermal wipe sampling of equipment.

Task 5 will include calculating the theoretical excess cancer risk from exposure to carcinogenic materials for each SEG determined from Tasks 2 and 4 and toxicity criteria relevant for California risk assessments. The risk assessment will result in an estimate of the probability of developing cancer as a result of exposure, expressed in terms of the numbers of people out of one million. Varying degrees of conservatism will be added to this approach to ensure that cancer risk is not underestimated, which makes it probable that potential risk will be overestimated.

Task 6 may include analyzing public comments, explaining the rationale for specific policy recommendations, and disseminating the study findings to the Governor, Legislature, Occupational Safety and Health Standards Board, Los Angeles County Board of Supervisors, and stakeholders in the workers' compensation system.

#### 1 Background and Rationale

Cancer risks from occupational exposures associated with firefighting have been assessed and described in the literature (IARC, 2010), and firefighters are included in the California Cancer Presumption for worker compensation purposes (Labor Code §3212.1). In comparison, for firefighting equipment mechanics and cleaners, there is limited information on potential occupational exposures and cancers observed.

The purpose of Task 1 is to identify and review relevant published literature to understand the state of the science with respect to exposure to chemical carcinogens associated with repairing and cleaning firefighting vehicles and equipment, as well as studies of cancer risk among fire mechanics.

#### 2 Objectives

The objectives of this literature review are as follows:

- 1. Identify carcinogenic chemicals of potential concern (COPCs) for mechanics who repair and clean firefighting vehicles and equipment
- 2. Identify epidemiologic studies evaluating the risk of cancer among mechanics who repair and clean firefighting vehicles and equipment.

The structured literature review results will be used to guide the activities of the latter tasks.

#### 3 Methods for Data Collection

Standard guidelines to conduct structured literature reviews, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines, will be followed in the conduct of this review (Moher et al., 2009). These guidelines are widely accepted as the standard for conducting and reporting systematic literature reviews (SLRs). More than 170 journals in the health sciences endorse and require PRISMA for the reporting of SLRs and meta-analyses.

#### 3.1 Study Eligibility

Articles published through the date of the search with no lower date limit will be included in the review. Studies published in English as either peer-reviewed journal articles or conference abstracts will be eligible.

The following additional inclusion criteria will be employed to determine study eligibility for Objective 1:

- Population: Mechanics who repair and clean firefighting vehicles
- Exposure: Occupational exposures to potential chemical carcinogens
- Comparator: General population, non-exposed worker populations (e.g., office workers within firefighting discipline), workers with lower exposures
- Outcome: Any exposure measure or medical outcome
- Study Design: Industrial hygiene studies, exposure studies

The exclusion criteria to determine study eligibility are as follows:

- Population: No exclusions
- Exposure: Non-occupational exposures to chemical carcinogens; occupational exposure to non-carcinogens
- Comparator: No exclusions
- Outcome: No exclusions
- Study Design: Opinion pieces, reviews.

The following additional inclusion criteria will be employed to determine study eligibility for Objective 2:

- Population: Mechanics who repair and clean firefighting vehicles
- Exposure: Occupational exposures to potential chemical carcinogens
- Comparator: General population, non-exposed worker populations (e.g., office workers within firefighting discipline), workers with lower exposures
- Outcome: Cancer (any)
- Study Design: Cohort, case-control, case studies or case series

The exclusion criteria to determine study eligibility are as follows:

- Population: No exclusions
- Exposure: Non-occupational exposures to chemical carcinogens
- Comparator: No control group
- Outcome: Non-cancer outcomes
- Study Design: Opinion pieces, reviews.

The bibliographies of relevant reviews and publications will be hand-searched for additional citations of interest. If more than one article from the same study population was published, data from the publication with the longest follow-up or most specifically relevant population and/or outcomes will be extracted. For studies with overlapping data, those

with the larger population size or specifically relevant population and/or outcomes will be considered.

#### 3.2 Literature Searches

Databases to be searched include PubMed and Embase. The search strategy will be adapted to meet the search specifications of each included database. The search strategy includes search terms, language specifications, and other suitable filters for each database searched, and is designed such that outcomes of interest and possible stratification variables will be captured in the scope of the literature review. These will be translated into indexed Medical Subject Headings (MeSHs) and plain-language text-word terms using the National Library of Medicine MeSH thesaurus. The selected terms will be compared to index terms of related published studies to ensure that there are no gaps in the chosen search language. Boolean operators will be used to combine the final list of search terms into a comprehensive search strategy. As a final step, limit terms/filters will be added to the search strategy (e.g., English language) to ensure that only the most relevant studies are included in the final search yield. A draft search strategy is included as Section 3.3.

#### 3.3 Search Strategy

Due to the extremely limited number of studies identified in a scoping search, the final search strategy will employ a two-pronged approach:

**Step 1.** Conduct a primary literature search in PubMed and Embase to identify studies on exposures in fire stations, as well as general firefighting exposures that have been linked with cancer outcomes, in order to identify potential chemicals of concern for vehicle mechanics, using the search syntax shown in Table A.

Table A. Search Syntax for Step 1.

| Database | Search Syntax                                                                                                                                                                                                                                                                                                                                                                             |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PubMed   | ("fire station" or "fire department" or "fire fighter*" or firefighter*)  AND ("truck bay" or garage or maintenance or mechanic or helicopter or vehicle or "fire truck" OR "occupational exposure")  AND (exposure OR cancer[MeSH Terms] OR cancer OR carcinogen[MeSH Terms] or carcinogen*)                                                                                             |
|          | Pilot search on 6/25 yielded 203 results.                                                                                                                                                                                                                                                                                                                                                 |
| Embase   | ('fire station' OR 'fire department' OR 'fire fighter*' OR firefighter*)  AND ('truck bay' OR 'garage'/exp OR garage OR 'maintenance'/exp  OR maintenance OR 'mechanic'/exp OR mechanic OR 'vehicle'/exp  OR helicopter OR vehicle OR 'fire truck' OR 'occupational  exposure'/exp OR 'occupational exposure') AND ('exposure'/exp OR  exposure OR 'cancer'/exp OR cancer OR carcinogen*) |
|          | Pilot search on 6/25 yielded 148 results (138 potential duplicates from Medline)                                                                                                                                                                                                                                                                                                          |

**Step 2.** Conduct a primary literature search in PubMed and Embase for epidemiological studies of specific cancers identified in Step 1, evaluating all occupations, which may include mechanics or other trades that could work on vehicles and/or in fire stations.

Typically, three types of epidemiologic studies are of interest for occupational cancer reviews:

- 1. Cohorts of specific occupations that evaluate the incidence of all cancers
- 2. Case-control studies of specific cancers that evaluate all occupations
- 3. Large-scale studies that evaluate all occupations and all cancers.

Standard search strings (as we have specified in Step 1 above) will pull relevant studies in the type 1 category. However, it is important to note that not all studies in the type 2 category would be identified from the search if the cancer outcome results for firefighting mechanics are not significantly elevated and are reported only in the tables of the published literature. Hence, for this project, we will include the additional strategy of identifying specific cancers of interest and subsequently searching for studies that evaluate the risk of these cancers by occupation (type 2 studies). Finally, we plan to evaluate the epidemiologic literature from reports by IARC, NIOSH, and other agencies, as well as large-scale occupational cohort studies from Nordic countries (type 3 studies). Search syntax for Step 2 are shown in Table B (pilot searching was not performed for these searches).

Table B. Search Syntax for Step 2.

| Query          | Search Syntax                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------|
| Cancer cohorts | (lymphoma OR prostate OR testicular) AND cancer AND "occupational exposure" AND (cohort or "case-control") |
| Nordic cohorts | (Nordic OR Scandinavian) AND cohort AND occupation AND cancer                                              |

#### 3.4 Study Selection

Study selection will be documented through DistillerSR, a specialized software program designed for tracking and managing literature reviews, resulting in a fully auditable and transparent review process. A PRISMA flow diagram will be included in the study report detailing the flow of study inclusion and exclusion at each study level, including reasons for exclusion at the level of full-text review.

Review of studies will begin at the level of title and abstract. Reviewers will screen the titles and abstracts of the studies produced by the literature searches (after de-duplication) to determine their relevance for this review. Studies will be screened against the inclusion and exclusion criteria for study population, interventions, outcomes, and study design for each objective.

Articles designated as relevant from the title and abstract review will proceed to full-text review, where researchers will evaluate the full text of the article for relevance. Studies will again be screened against the inclusion and exclusion criteria, excluding case reports, case series with <20 patients, opinion pieces, studies published in languages other than English, and reviews. Relevant reviews will be identified during the full-text review, and the bibliographies will be hand-searched for additional citations of interest. Each study will be evaluated at the level of full-text review, by two reviewers independently, to determine agreement on included articles (100% QC). All disputes will be resolved by consensus adjudication. The results will be recorded, maintained, and assessed using DistillerSR.

#### 3.5 Data Abstraction for Step 1 Search.

Data will be abstracted in DistillerSR for all studies from Step 1 (as described in Section 3.3) deemed relevant to the review in the full-text review stage. The abstraction form will be reviewed prior to any data abstraction to ensure that all appropriate fields are captured, and an initial small sample of articles will be extracted to determine whether the form captures the appropriate information from the articles.

Anticipated data abstraction elements are as follows:

- General information, including title, authors, and year of publication
- Study characteristics:

- By person (demographics, job, confounders)
- By place (geography, workplace/facility)
- By time (calendar years of conducted study and follow-up)

#### Outcomes

- Objective 1: Occupational exposures (chemical, exposure levels)
- Objective 2: Cancer-related outcomes (numbers, incidence rate, mortality rate, odds ratios, risk ratios, hazard ratios, standardized incidence ratios, standardized mortality ratios).

#### 3.6 Study Selection and Data Abstraction for Step 2 Search.

Studies identified during our supplemental searches (as described in Section 3.3, Step 2) will be reviewed for relevance at the title and abstract level; relevant full-text studies will be searched for data for fire mechanics. Due to the volume of studies anticipated for the cancer cohorts search, we will use the Sciome Workbench for Interactive computer-Facilitated Text-mining (SWIFT-Review) interactive text-mining tool to scan titles, abstracts, keywords, MeSH annotations, and SWIFT-generated tags for the following syntax: "occupational AND cohort AND cancer AND occupations," "fire AND (maintenance OR cleaning OR mechanic)," and "mechanic AND cohort."

Studies from the supplemental search that appear relevant but do not meet the objectives inclusion criteria will be summarized and cited within the report but not included in the data abstraction table.

#### 3.7 Data Synthesis

A narrative summary of the review, including the methods and results for each outcome identified in the literature review, will be developed.

Possible elements include:

- Identification of COPCs
- Work tasks associated with exposures to COPCs
- Characterization of important confounding factors and biases
- Significant cancer outcomes associated with occupational exposures among this worker population
- Strengths and limitations of studies.

#### 3.8 Limitations of Review

This review will be limited to peer-reviewed journal articles and conference abstracts published in English. Information published in the grey literature will be excluded. The results

of this review may be generalizable only to the geographic areas and populations included in the studies.

#### 3.9 Dissemination of Results

The results of this review will be submitted to the State of California Department of Industrial Relations under Assembly Bill No. 1400. Specifically, the deliverables will include:

- EndNote library of the relevant publications
- Data abstraction file of included studies
- Written summary of the state of science.

The summary will include a list of COPCs and descriptions of work tasks that may result in exposure to the substance(s), with citations to specific publications. Cancers reported in this worker population will be also described. The results may also be submitted as a conference abstract to a relevant conference.

| Chung, J., Denners, P. T. L. T. L.       | Career fire hall exposures to diesel 2020<br>engine exhaust in Ontano.<br>Canada                 | 2020 | Ontario.<br>Canada                               | The study to blective was to evaluate diesel engine exhaust (DEE) levels in career fre hals in Ontario, Canada.                                                                                                                                                                                      | The study objective was to evaluate clese  The study objective was to evaluate clese  The results show that fired study continues and the study oppulation consisted of 12 and a season of applicant (LEV) units  Although no cocupational exposure limit for DEE and a Time falls were selected if and continue to implement DEE control isrategies to character the half was the fire that responded to the reduce exposures to mitgate potential health risks. Inferent building design that had a moderate to high call volume. | The study oppulation consisted of 12 carear fine hals from six different clies (City,-City,) within the province of Ontano. Canada. Two fine hals were selected in each participating off through consultations with participating fire opparitients. The first hall selected in each opportunitients with participating fire opparations with participating fire opparations with participating fire participating fire participating fire first hall selected in each right selected was a hall with a fire separate for identifying the number of mines for expensive selected was a hall with a different building design that had a moderate to high call volume. | Respirable elemental extra rotino (REC) was neasured using a modified MIOS4 analytical method (e.g., method 5040) for diesel plantical method. The MIOS4 analytical method of the MIOS4 an |
| Echt. A. Sheelty,<br>J., Blade, L.       | Exposure to diesel exhaust manasions at three fire stations: Evaluation and recommended controls | 1995 | Not specified;<br>authors are<br>located in Ohio | Not specified: The National Institute for Occupational Safety Juthors are and Heatht (NIOSH) conducted a health hazard evaluation (HFE) at three engine houses of a municipal fine department to evaluate exposure to diese levaluaties exposure to diese expartment emissions in the engine houses. | When diesek-powered equipment leaves or returns from a neighe house, exhaust ensisons containing diesel particulate are produced inside the agreatuse bay, the felsel exhaust can then enter the living quarters. The agreement of current toxicological and epidemiological evidence suggests that occupational exposure to diesel exhaust is a potential cardinogen.                                                                                                                                                              | Personal breathing zone and general area al samples for elemental carbon were collected at all three engine houses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | At each engine house, samples were collected in the breathing zones of an officer and two other enjoyees (either fire fighters, medicine fighters, medicine fighters, medicine fighters, medicis, or medic traines). To evaluate the exposures that occurred the the enjoy and exclude those that occurred while right the mengen to when their wehicle cleaned the engine house doors and turn the pumps on when the wehicle began backing into the engine house upon their return. Area samplies were also collected at each engine house.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Chung, J. Demers, P. A. Kalenge, S., Kirkham, T. L. | Caneer fire hall exposures to diesel 2020 engine exhaust in Ontario.                             |       |                                                  |                                                                                                | Respirable elemental carbon (REC) as a surrogate for diesel engine exhaust (DEE)         |                                                                                                                                              |                         |                                                                   | Of the 69 samples collected : 16% had detectable elemental carbon concentrations, where all but one was taken within the vehicle bay diesgo6.5 mg/lin-2.7 mg/lin-3. The data inclicates vehicle bay texposures may be higher in hals with LEV units, those that respond to none emergencies, have a backen vehicle bay design compared to driventhough design, and during the summer season. Three samples (4.3%) socaeded the cocapational exposure limit however, the estimated exceedence reaction of the underlying whiche bay exposure distribution was 17%. Eight mals had LEV units, where performance ranged from 3.6% to 85.3% (median= 54%) when compared to manufactuer recommendations. |

P., Dalton, J. | Title  Volatile organic compounds off- gassing from firefighters' personal profective equipment ensembles after use | <b>Year</b><br>2015 | Geographic<br>location of<br>study:<br>Chicago,<br>Illinois | Author's objective The author's conclusion The study were to The overhaul and off-gas air concentrations w The study were to The concentration and composition of well below applicable short-term occupational Valettle organic compounds (VOCs) off — Exposure Imitis. Compounds to pre-but heve, The concentration of the concentration | Author's conclusion The overhall and off-gas air concentrations were well below applicable short-term occupational was below applicable short-term occupational authors measured ~2 fold increases in mean breath                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Study design: This experiment consisted of three controlled structure burns that took place inside an intermodal metal container with two rooms made of drivwall. New drywall                                                                                                                                                                                                                                   | Data collection methods used: Sampling VOCs off-gressing from PPE Ensembles: Approximately 25 minutes after completing overhaul for each controlled burn, the two nesembles (except for SGBA) were placed inside the clean nericosures along with evacuated canisters to collect off-gas samples                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                                                                                                   |                                                                                                                     |                     |                                                             | ions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | and contentiations of betrazen, cludine, and styrene after the burns. Air concentrations of benzene, toluene, ethylbenzene, xylenes, and styrene toluene, ethylbenzene, xylenes, and styrene toluene (TSY) measured off-gassing from finelighters used EPE and in firelighters position exhaled breath were significantly corrielated.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | was erected for each burn. The sampling performed included: all sampling inside the structure, off-gas sampling, and exhaled breath sampling. The main purpose of the sampling was to determine the magnitude and composition of VOCAs that were generated during the fires, subsequently def-gassed from the firefless ensembles, and systemically absorbed by the fireflighters and exhaled in their breath.  | over 15 minutes to perform comparison with stork-term occupational approars in minutes to perform comparison to a special minus (OELs). Using the same method, they also did tousens as the control.  VOCs were sampled of spassing of brand-new fumout coats and trousens do the sampled brands are the structure (during semi-votatile PAHs, were sampled in skinled compounds, including semi-votatile PAHs, were sampled in skinled breath approximately 4-14 minutes after completion of overhaul for each burn (2-10 minutes after finelighters doffed their PPE).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Fronse, J. R. Hinds, W. C. Duffy, R. M. Laftente, E. J. Lu, W. C. Y.                              | Exposure of frefighters to diesel emissions in fre stations                                                         | 1987                | New York. Boston, and Los Angeles                           | Af the request of the International Association of Fire Fighters and the Los Angeles, Boston and New York free departments, the authors conducted a study of freelighter exposure to diesel particulatios in free stations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | For the tan fire stations sampled, the major contributor to the measured leves of fotal particulates was the diese temssors from the fire particulates was the diese temssors from the fire some sets of the stationary of the stati | Personal sampling of frieighters was used for measure exposure to troll airborne particulates in the ten fire stations. Representables samples were collected at fife trucks and skife free places, five fifer trucks and skife replaces. A real-line aerosol monitor (RAM-1, GCA Corp.) was airborne particulates on the vehicle froor airborned truck and engine at drivers entry of a New York fire station. | Personal sampling was used to measure exposure to total airborne particulates in the fire stations: Dp Pont P 2500 purps; Qu Pont Company) were used at a flow vitae of 2 Limin. Telbroi-coated glass filed filters were used at a flow vitae of 2 Limin. Telbroi-coated glass flow filters were used to determine the methylene chloride soluble farcation of the total particulates. Pumps were calibrated before and fafter each 8-th sampling period.  There was a study team member in each fire station to observe pumps' performance continually. Stations in New York and Boston were sampled for district the predict. One New York station was sampled to 164 hr. About five fireflighters were sampled during each 8-th period. For station and period of the arrowed their pumps before leaving the fire station to respond to an alaim. Pumps were laken to an office that was located away from the fire station equipment floor and continued to operate in this area. Upon return to the station, each fireflighter stands wering this pump again. In the station, each fireflighter stands wering this pump again, an owned operating conflicions, the authors also estimated the most severe exposure to deset particulates that a fireflighter might retrounter during an 8-th reflord in a Los Angeles file station. It was clearly on each of a lower to the station with all the truck and engine were turned on and allowed to idle for fire station. It was determined that the wind over and doors in the fire station during this simulated exposure. Personal sampling of nine fireflighters was conducted over the 8-tr stiff to assess individual exposures. |

P., Dalton, J. | Title gassing from frefighters' personal protective equipment ensembles after use | Year 2015 | Geographic location of study: Study: Chicago, Illinois | What potential carcinogens an are reported? > Benzene es Benzene | What potential carcinogens are reported? > Diesel                                                                                                     | What potential carcinogens The reported? > Polycyclic of aromatic Hydrocarbons (PAHs) | What potential carcinogens are reported? > are reported? > potential diphenyls organophicine pesticides (OCPs) (OCPs) | What potential carcinogens are reported? > Other (Specify) VOCs. 1 4 dichlorobenzene, ethylbenzene, styrene | What exposure information is reported?  Ar Concentrations of VOCS off-gassing from PPE Ensembles. The air concentrations measured from used PPE ensembles were generally higher than the background levels, with statistically againfrient differences (P < 0.05) observed for accident 1.4-dichlorobenzene, and cyclohexane. Of note, the off-gassing air concentration of 1.4-dichlorobenzene was higher for the brand new turnout cost and trousers than the used PPE ensembles. All air concentrations were well below any applicable short term OELs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Froines, J. R., Hinds, W. C., Duffy, R. M., Laftbente, E. J., Llu, W. C. V.            | Exposure of freighters to desei emissions in fire stations                        | 1987      | New York.<br>Boston, and<br>Los Angeles                | - E                                                              | Total airbome particulate matter (the major contributor to the measured levels of total particulates was the diesel emissions from the free vehicles) |                                                                                       |                                                                                                                       |                                                                                                             | The data presented show that firefighters are exposed to increased levels of particularities rim diseal emissions. The levels of total attorne particularies ranged from particularies from diseal emissions. The levels of total attorne particularies angod from how you golm? to as high as 480 µg/m². Firefighter exposure to total particularies increased with the number of runs conducted during an 8-hr period. In New York and Boston where the response levels do from 10 of 10 µg/m² for diseal particularies where for the seal and period from 70 of 10 µg/m² (TWA). The important sources of particularies beyond those produced by the diseap-owered vehicles were cooking furmes, ambient aerosal and cigarelie smoke. Methylene chloride extracts of the diseal particulates surged 24% of the total.  Smoking controlling 12 burdeen percent of the firefighters sampled were smokers. Smoking controlling 10 burdeen percent of the firefighters sampled were smokers. Smoking controlling 10 burdeen percent of the firefighters sampled were smokers. Baccause of winter weather conditions, doors and windows of fire stations in New York and Boston were kept chose of the sampling genders except and because of the firefighters were effect open. The sample of the sampling genders were effect open. The sample are sampling equipment at the sound of an alarm as previously descentable, the sampling equipment at the sound of an alarm as previously descentable, the sampling equipment of dieseal exhaust underestimates the personal exposure concentration. During this pender for the vehicle or gathering equipment and the whole to operate away from the reliable or gathering equipment of the vehicle Descele burger of the vehicle or gathering equipment and not he vehicle. But the sample gate of highest concentration to the vehicle or pastering equipment and not he vehicle. |

Formaldehyde was the predominant aldehyde detected in fire smoke, both at flaming and smoldening fires. Results of TWA sampling include that formaldehyde levels are likely to these excursions above 0.37 mg/m² (0.3 ppm), which may result in eye or respiratory mitation.  Polycyclic anomatic hydroactbons, some of them known to be carcinogenic, were of polycyclic anomatic hydroactbons, some of them known to be carcinogenic, were detected in fire smoke at very low levels. Similarly, limited benzene sampling generally indicated tow or nondetectable levels; however, one sample exceeded 0.1 ppm, which has recently been proposed as a new TLV because of benzene's carcinogenic potential.                                                                                                                                                                                                                                                                                                                                                                             |
| Park, L. S., Voss, R.<br>W., McHeel, S., Wu,<br>N. Guo, T., Weng,<br>Y., Israel, L., Das,<br>R., Petrass, M. | firefightes to polybrominated diphentyl ethers             | 2015 | Southem                               |                                             |                                                                  |                                                                                                                                                       | polychomate biphranate biphranate biphranate biphranate pesticides (PCBs; PCBs; PCBs | Organochiorine pesticides<br>(OCPs), B-BHC<br>(Hexachloroxyclohexane), 4,4''.<br>DDT, 4,4''.DDE,<br>DDT, 4,4''.DDE,<br>norabilor, oxycliodane<br>norabilor, oxycliodane<br>(Chlordane is the parent<br>compound of trans-nonachlor<br>and oxychlordane) |                                                             | Many PCB and OCP congenes conneited with each other but not with the major PBBEs, supporting the hypothesis that exposure pathways for PCBs and OCPs are different from those for PBDEs. This study suggests that freighting is not a significant source of exposure to PCBs and OCPs. PBDEs may be transported back to fine astations on equipment (hoses, laddens, and 805A) and clothing. Contact with solied turnout gear and exposure opportunity during other and storage at the fine station. This research shows very high PBDE levels in first station dust (e.g., media BDE-209 (right) 4.7 (100% 2.50 oin Callionia revisionist Lebs and OCPs, but not PBDEs, were lower among freighters whose variedinated broate dust), which suggests that when freighters exturn to the fire station, murdut gear was professionally decontaminated in the past year. Decreases (and patients) growing the PGB-180, could be considered many freighters whose transport freighters whose transport freighters whose transports of the past year. Decreases (and patients) growing the patient properties of the past year. Decreases (and patients) and the past year than expendent of the past year. Because of 30% with more freighters than dwesting furning urmout gear at the firehouse or storing it is an open room (versus a personal locker) had lower serum levels of BDE-28, 47, 59, and -100. |

| Author<br>Shan, B.,Whitehead, T.<br>P., Medeel, S.,Brown, F.<br>R.,Das, R., Israel, L., Park,<br>J. S.,Petreas, M. | Trite Measurements of PAHs, PBDEs, and PCBs in dust from California firehouses                       | 2012 | Geographic location of study: Callonia | Author's objective Freelighters are exposed to a unique profile of potentially free-telated character, considered contaminants, including doxins, antimony, and other metals, as demonstrated by be-montloning studies. In this plot study, the authors measured concentrations of PAHS, PBDEs, and PCBs in dust form 20 calient in freely less of the possible that frefighters carry dust contaminated with PAHs and PBDEs into their contaminates on their books and protective clothing after extinguishing frees. | Author's conclusion Concentrations of PAHs and PBDEs are much Concentrations of PAHs and PBDEs are much higher in dust from California behouses than in house dust from California homes, suggesting that house dust from California homes, suggesting that sources. Concentrations of PBDEs in dust from California frehouses were orders of magnitude higher than concentrations of PAHs and PCBs in the same samples.                                                                                                                               | Study design: Dust samples were collected from the Evacuum cleaner bags used in the living quarters of 20 California frehouses in 2011 and in 2011.                                                                                                                                                                         | Data collection methods used: Breity, the samples were sleved to remove fibers and debris larger than 150 µm. The resulting fine data was allyqueffer (0.2 g) and spiked with a mixture of labeled internal standards (1 PAH, 8 PBDEs, 15 PDEs, and 2 pesiblicates) and extended by accelerated solvent inspectages and or self-stopphynass spectrometry (EFCAMS, Aglent Teachnologies), PBDEs and PDEs were analyzed tor PAHs using low-resolution electron impactages chromatographynass spectrometry (EFCAMS, Aglent Teachnologies), PBDEs and PDEs were analyzed using high resolution EI-CAMS (Thermefringan wMT95). The shorional institute of Standards and Technology Standard Reference Material (NIST SRM) No. 2585 was used in each run for additional quality control.                                                                                                                                                                                                                               |
| Shen, B.,Whitehead, T. P.,Mohele, S.,Bown, F. R., Chalwal, J., Das, R., Israel, L., Park, J. S., Petreas, M.       | High levels of polybrominated diphenyl ethers in vacuum cleaner dust from California fire stations   | 2015 | California                             | Concentrations of polybrominated dipheny effects (PBES), but you'golis annatic hydrocarbons (PARs), and polycypilic annatic hydrocarbons (PARs), and polycypilic annatic highlenys (PCBS) were measured in dust from 20 Cellifornii er sistations. The chemical concentrations in fire sistation at sistation dust were compared to concentrations previously reported in dust from residences and other occupational settings worldwide.                                                                              | BDE-209 concentrations in dust from California fine activations were among the highest of any previously documented formes or occupational settings in the world. Based on the findings of the pilot study, the world. Based on the findings of the pilot study, the surrors hypotheses that possible sources of BDE-209 in fire stations include confaminated ash and there deak thorn fine events via boots, clothing, and other equipment as well as specialized and other equipment treated with BDE-209, including tumout gear and fire vehicles. | In 2010-2011, dust samples from used from a vacuum cleanter bags, were collected from a 20 fire stations in California and analyzed is for polybrominated dipheraly eithers. Please, by collected by the collection of PABS, and polybriomated bipherals in PABS, using gas chromatography—mass is spectrometry.            | Dust samples were collected from vacuum deaners used in the living and administrative or quarkers of the fire stations; dust samples were saved to remove large debris and then underwent chemical analysis. Extracts were analyzed for 22 PBDEs and 16 PCBs using high-resolution; gas chromotography-mass spectrometry operated with electron impact onization mode. In addition, during dust collection, a two part on-site survey was conducted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Sparer E<br>H., Perdergast, D. Apell,<br>I., N. Bartzak, M.<br>R., Waberer, G.<br>J. E., Sorensen, G.              | Assessment of Ambient Assources Freighters Encounter while at the Fire Staton: An Explorationy Study | 2017 | Massachusetts                          | 1) to provide preliminary data on the air quality within a few the stations in and around Boston, Massachusettis; and, 2) to investigate some of the environmental and organizational factors that may influence the levels of contaminants in the air at the fire stations.                                                                                                                                                                                                                                           | Levels of PM <sub>2</sub> , and PAH inside fire stations may according to the stations may mornture to firelighter cancer static. Through undestanding contaminant variability, future studies can begin to design and test interventions that improve cancer prevention.                                                                                                                                                                                                                                                                              | At sampling of particulate matter less than 5.2 bm in diameter (Ph.) 2 and particle bound polycyclic aromatic hydrocarbons by CPAIs) was completed at four fire stations in Spring, 2016. There fire stations were located in Boston, Massachuserits, and one fire station was located in Admigron, just outside of Boston. | sampling included integrated and continuous measurements of particular entate (PM2), and continuous measurements of particles bound polycyclic annate bydractabons (PAH8) in three primary areas in and annual the station; the truck bay, the kitchen, and outside. Gawmente PMs, samples were collected using Tethon filters (47mm, Pail Life Sciences, Port Washington, NY, USA) used with an impactor cassette for measure PMs, samples were measured with a SidePak Aerosol Oomlinuous-readings of PMs, awere measured with a SidePak Aerosol Monitor Aktor (TSI, Minerapolis, MX).  2000CE (EcoChem Analytics, League City, TX) interviews: The purpose of the interviews was to understand the daily activities. The purpose of the interviews was to understand the daily activities of freighters, along with the policies and practices (both written and enabled) regarding engine ide-time, return and washing of contaminated clothing, and any other station-related health and safety activities. |

Marrica.  BDE-209 was the predominant PBDE congener measured in the California frehouses followed by BDE-98, BBC-47, BBE-101, BBE-153, BBC-208 and to a lesser extent, BBE-154, BBC-207, and BBE-209. The levels of BDE-209 measured in the California frehouses (maximum of 390 µg/g) are among the highest ever reported.  PCB concentrations in California frehouses were more consistent across congeners and ware dominated by 3 congeners. PCB-153, PCB-138, and PCB-180, PCB levels in California frehouses were comparable to PCB levels seen in Northern California residences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Shen, B. Whitehead, T. H<br>P.,McNeel, S.,Brwn, F. di<br>R.,Dhalwal, J.,Das,<br>R.,Israel, L.,Park, J.<br>S.,Petreas, M.   | High levels of polybrominated diphenyl ethers in vacuum deaner dust from California fire stations                                     | 2015 | California                          |                                                        |                                                               | Polycyclic aomatic Hydrocarbons (PAHS): benzolg lanthracene. ordhysene. benzolg fillouranthene, benzolg fillouranthene, benzolg fillouranthene, denzolg fillouranthene, denzol | polychlormated biphenys<br>(PCBs) PCB-28, PCB-32,<br>PCB-101, PCB-105, PCB-118,<br>PCB-180 |                                                                              |                                                            | In general concentrations of PBDEs were higher than concentrations of PAHs and concentrations of PAHs were higher than concentrations of PAHs were higher than concentrations of PGBs in the fire stations, Each of three major PBDE congenes had median dust concentrations above 5000 ng/gl Gir Norgio for BDE-209 and 47000 high of PBDE-209. BDE-209 was the predominant PBDE congener measured in the dust from these fire stations. Median concentrations of PBDEs and PAHs in the fire station dust samples were substantially highratine and the same analytical protocols.  Correlations with the number of fire or hazardous meterial incidents, or fire station age, are presented in Table 2. The correlation substance chemicals and the number of vehicles in the fire station was not statistically significant.  Softwared positive relationships between PCB levels and fire station age are consistent with similar observations in California homes and suggest that the PCB-contaminated materials may still be present in fire stations built before the 1970s, when PCBs were                                                                                                                                                                                                                                                       |

The average daily PMs,s levels (using the gravimetric data) in the truck bay were also on higher than outside, when adjusting for the other stations; and this association was statistically significant (g=10.74 µg/m², p-value = 0.028). The intervelses also indicated that practices surrounding washing of bunker gear varied from station to station. Oif-gassing from equipment post-fire might be another source of intention are of Station #4 and PMs,s observed in the truck bay of Station #4 and pwd, proper at Station #4 allowed for some freighters to sancke while at work. These freighters had entered the department prior to 1988 and therefore were grandfathred in to the older department blosscop policy. These freighters planned their shifts together and, while at work, smoked digars inside the truck bay. |

#### 1 Background and Rationale

ToxStrategies was contracted by the California Department of Industrial Relations (DIR), Commission on Health and Safety and Workers' Compensation (CHSWC), to conduct the study as outlined in California Assembly Bill (AB) 1400. AB 1400 was created to define the fire mechanics' risk of exposures to carcinogens in the course of employment. The study components include:

- Site visits to representative facilities in Los Angeles County, California
- Interviews and surveys with current and former fire mechanics
- Feasibility study to assess cancer incidence among fire mechanics
- Occupational exposure measurements of carcinogens found in the workplace, to evaluate potential exposure to carcinogenic materials
- Quantitative health risk assessment of potential increased cancer risk associated with exposure to carcinogens in the workplace.

ToxStrategies' approach to address these study components includes six tasks (provided in our proposal submitted to the DIR [ToxStrategies, Inc., 2020a]):

- Task 1: Structured literature review submitted and summarized below; ToxStrategies, Inc., 2020b
- Task 2: Qualitative exposure assessment provided herein
- Task 3: Epidemiologic assessment feasibility study of cohort enumeration for future epidemiologic study design
- Task 4: Quantitative exposure assessment measurement of current occupational exposures to carcinogens
- Task 5: Cancer risk assessment calculation of theoretical excess cancer risks from occupational exposure to carcinogens
- Task 6: Technical assistance to the DIR.

The results from Task 1, Structured literature review, demonstrated the paucity of literature available for characterizing potential carcinogenic exposures and cancer risks (epidemiologic studies) of fire mechanics. Occupation as a fire mechanic and risk of cancer has not been evaluated in the current scientific literature. No occupational chemical exposure studies explicitly focused on fire mechanics, fire mechanic cleaners, or fire-fighting vehicle maintenance workers. However, nine industrial hygiene studies presented data for fire stations and firefighting vehicles and/or gear, which likely overlap with the occupational exposures of fire mechanics who repair and clean firefighting vehicles. The chemical carcinogens evaluated in these studies included benzene, diesel exhaust, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs), acetaldehyde, formaldehyde, crystalline silica, 1,4-dichlorobenzene, ethylbenzene, and styrene.

The purpose of Task 2, Qualitative Exposure Assessment, was to determine similar exposure groups (SEGs) among the fire mechanics and prioritize/define the scope of the quantitative exposure assessment, based on a risk ranking that incorporates the relative magnitude of the exposure potential, specifically for carcinogens (AIHA, 2015).

The objectives, methods, results, and conclusions of Task 2, Qualitative exposure assessment, are provided below. The remaining study tasks are described in Section 6.

#### 2 Objectives

The objectives of this qualitative exposure assessment were as follows:

- 1. Identify the fire mechanics' main facilities of operation within the County of Los Angeles Fire Department
- 2. Determine SEGs among the fire mechanics and determine representative exposure parameters
- 3. Provide an exposure ranking for each SEG to carcinogens identified in the facilities in order to prioritize the quantitative exposure assessment to those exposures that may pose the highest risk.

#### 3 Methods

ToxStrategies identified the County of Los Angeles Fire Department mechanics' classifications and three main facilities of operation with the assistance of member leaders from the American Federation of State, County & Municipal Employees (AFSCME) Local 119. The member leaders of AFSCME Local 119 included Mr. Gary Hodge, President of Union Local 119; Mr. Andreas Jung, President of Southern California District Council 36; and Luis Del Cid, member of Union Local 119.

The three main facilities of operation include:

- Eastern Fire Shop, located at 1104 N Eastern Avenue, Los Angeles, 90063
- North County Fire Shop, located at 42110 6th Street West, Lancaster, 93534
- Pacoima Air Operations/Breathing Apparatus (BA) Shop, located at 12605
   Osborne Street, Pacoima 91331.

AFSCME Local 119 union members include Automotive/Helicopter Mechanics and Equipment Maintenance Workers and Repairmen, employed by the County of Los Angeles (http://www.afscme36.org/afscme-local-119).

The four fire mechanic classifications are (1) Equipment Maintenance Worker, (2) Fire Equipment Mechanic (FEM), (3) Helicopter Mechanic, and (4) Helicopter Maintenance Inspector.

#### 3.1 Site Visits and Personnel Interviews

Site visits were conducted on September 15 and 16, 2020, by Ms. Deborah Proctor and Ms. Stephanie Vivanco of ToxStrategies. The purpose of the site visits (walk-around surveys) and personnel interviews (in-person and conference calls that occurred after the in-person site visits) was to gather information regarding chemical exposures of fire mechanics by recording observations of potential sources of exposures to chemical carcinogens at each location, as well as the manner in which these exposures may occur. The survey approach included identifying chemical agents in the workplace and discussing the overall job and specific work tasks conducted by each of the fire mechanic classifications. The survey goals were to understand how and when workers are exposed to the chemical agents, ascertain information regarding the availability and use of exposure controls (personal protective equipment [PPE], engineering/administrative controls, work practice controls), and discuss the evolution of chemical usage and work practices over time.

On September 15, Ms. Proctor and Ms. Vivanco visited Pacoima Air Operations and the Eastern Fire Shop. At Pacoima Air Operations, ToxStrategies, accompanied by Mr. Hodge, Mr. Jung, and Mr. Del Cid of AFSCME, met with Mr. Dennis Blumenthal, Chief Helicopter Maintenance of the Air Operations Section, who provided the facility tour and information regarding the various job tasks of helicopter mechanics at Air Operations. After the facility tour, ToxStrategies conducted in-person interviews with Mr. Tyrone Mathis, Helicopter Mechanic, and Mr. Brian Uhl, Helicopter Maintenance Inspector. Both Mr. Mathis and Mr. Uhl work at Pacoima Air Operations.

At the Eastern Fire Shop, ToxStrategies met with Deputy Fire Chief Thomas Ewald, Acting Division Chief Chad Idol; and Mr. Hodge and Mr. Del Cid of AFSCME. Mr. Hodge and Mr. Del Cid, both Fire Equipment Mechanics (shop-assigned at the Eastern Fire Shop), provided the facility tour and qualitative information on the typical job tasks of a Fire Equipment Mechanic. We also met with sheet metal assembly workers at the Eastern Shop.

On September 16, ToxStrategies visited the North County Fire Shop in Lancaster, California, and BA Shop in Pacoima, California. At the North County Fire Shop, ToxStrategies met with Mr. Mitch Connett, Assistant Chief of the Fire Fleet Services Division, along with Mr. Phillip De La Tova, Acting Senior Fire Equipment Mechanic (shop-assigned). Both Mr. Connett and Mr. De La Tova provided a facility tour, along with qualitative information on the typical job tasks. After the facility tour, ToxStrategies conducted an in-person interview with Mr. Neill Niblett, Fire Equipment Mechanic (field-assigned), and Mr. Niblett provided a tour of the Fire Station located on the same property as the North County Fire Shop in Lancaster (Fire Station 129).

At the BA Shop site visit, ToxStrategies met with Mr. Jared Snyder, Senior Equipment Maintenance Worker, who provided a facility tour and information regarding the typical

job tasks of an Equipment Maintenance Worker. The BA Shop includes mechanics who work on breathing apparatus and repair small engines and hoses.

On September 24, 2020, ToxStrategies conducted additional virtual interviews with the following personnel:

- Harry Wong, Fire Equipment Mechanic (field-assigned)
- Grant DeRose (known as "Sonny," now deceased), retired Fire Equipment Mechanic (field-assigned)
- Luis Del Cid, Fire Equipment Mechanic (shop-assigned), Eastern Fire Shop.

### 3.2 Records Review

ToxStrategies was provided copies of Safety Data Sheets (SDSs) used by the Fire Equipment Mechanics at the Eastern Fire Shop and the North County Fire Shop. However, SDSs for products used at the Pacoima Air Operations and BA Shop were not available; therefore, chemical usage information was obtained through the site visits and personnel interviews only.

No documentation regarding chemical usage changes over time was available for our review; however, anecdotal information was obtained through personnel interviews. The fire mechanic personnel who were interviewed for this project also stated that written process standards and operating procedures, health and safety programs, and employee exposure monitoring records are limited, and none could be provided to ToxStrategies. Therefore, our understanding of these issues is gleaned from personnel interviews.

## 3.3 Exposure Ranking for each SEG to Carcinogens

For jobs and tasks where potential exposure to a chemical carcinogen was identified, a qualitative exposure assessment tool was used to prioritize potential exposures, allowing ToxStrategies to target the DIR resources for Task 4 in the most cost-effective way. The tool was developed in accordance with the qualitative exposure assessment guidance from the National Institute for Occupational Safety and Health (NIOSH)<sup>2,3</sup> and the American Industrial Hygiene Association (AIHA, 2015). Information gathered from the site visits and personnel interviews was entered into a job task rating spreadsheet for each SEG (Attachment 1).

Each job task was characterized in terms of relevant chemical product usage information and/or fire residues encountered. The overall risk ranking was determined based on an exposure rating and health effect rating of the product and/or residue encountered by fire

https://www.cdc.gov/niosh/topics/oeb/default.html

<sup>3</sup> https://www.cdc.gov/niosh/topics/ctrlbanding/default.html

mechanics, by job task. Figure 1 shows the matrix that combines the exposure rating and health effect rating.

|                 | Health Effect Rating |     |          |      |           |
|-----------------|----------------------|-----|----------|------|-----------|
| Exposure Rating | 0                    | 1   | 2        | 3    | 4         |
| 4               |                      |     |          |      | Very High |
| 3               |                      |     |          | High |           |
| 2               |                      |     | Moderate |      |           |
| 1               |                      | Low |          |      |           |
| 0               | Trivial              |     |          |      |           |

Figure 1. Risk ranking matrix

Because carcinogen exposures were the focus of this assessment, only job tasks with carcinogen exposures are discussed below. Attachment 1-B presents the job task ranking spreadsheet for each SEG.

To calculate an overall risk rating, the following six steps were conducted:

1. The exposure rating was calculated by converting the job task frequency and duration to a points system, based on the matrix presented in Table 1. A low job task frequency and duration (e.g., >1/month and <15 minutes) yielded a lower point score (e.g., 1) than a job task with a higher job task frequency and duration. Columns B, C, and D of Attachment 1-B present the Task Duration, Task Frequency, and Frequency/Duration Rating, respectively.

Table 1. Job task frequency and duration rating system

|                      | Frequency of Job Task |                                                      |       |  |
|----------------------|-----------------------|------------------------------------------------------|-------|--|
| Job Task<br>Duration | >1/month              | >daily/<br><monthly< th=""><th>daily</th></monthly<> | daily |  |
| <15 min              | 1                     | 1                                                    | 1     |  |
| 15 min – 1 hr        | 1                     | 2                                                    | 2     |  |
| 1–2 hrs              | 1                     | 2                                                    | 3     |  |

| 2–4 hrs | 1 | 3 | 4 |
|---------|---|---|---|
| >4 hrs  | 1 | 4 | 5 |

Abbreviations: hr(s) = hour(s); min = minutes

2. A dispersion rating, indicative of a chemical's potential to be airborne, such that a worker could be exposed via inhalation, was determined by evaluating the vapor pressure of the individual carcinogens present in the product or identifying the carcinogen's dustiness factor (low, medium, or high, as described in Table 2). A low vapor pressure or "dustiness" (<25 mmHg [millimeters of mercury] or "low dustiness") yielded a lower dispersion rating than a high vapor pressure or "high dustiness," as shown on Table 2. In Attachment 1-B, column G presents the dispersion ratings for vapor pressure and dustiness for each job task.

Table 2. Dispersion rating system

| Chemical Vapor Pressure at 20°C or Dustiness Factor | Dispersion<br>Rating |
|-----------------------------------------------------|----------------------|
| <25 mmHg or 33 mbar                                 | 1                    |
| 25–100 mmHg or 33–133 mbar                          | 2                    |
| 100–250 mmHg or 133–333 mbar                        | 3                    |
| >250 mmHg or >333 mbar                              | 4                    |
| High Dustiness†: fine, light powders                | 4                    |
| Medium Dustiness†: crystalline granular solids      | 2                    |
| Low Dustiness†: Pellet-like, non-friable solids     | 1                    |

Abbreviations: mmHg = millimeters of mercury; mbar = millibar

3. An exposure control rating was determined by evaluating the job task engineering controls. Engineering controls are built into the workspace that protect the worker from harmful chemicals or contaminants by minimizing or eliminating its hazard (e.g., fume hood) (AIHA, 2015). For example, an open system with ineffective or no exposure controls yielded the highest control rating of "4," as shown on Table 3. Step 3 is also presented in columns H and I in Attachment 1-B.

<sup>†</sup> WHO, 1999.

Table 3. Level-of-control rating system

| Level of Control                                                                                                                               | Level-of-<br>Control<br>Rating |
|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Closed system; minimal potential for release to work environment                                                                               | 0                              |
| Semi-closed system; release potential at identified points; effective engineering controls in place at identified points                       | 1                              |
| Open system; effective engineering controls in place to contain/remove airborne contaminants; effective use of administrative and PPE controls | 2                              |
| Open system; some degree of engineering controls                                                                                               | 3                              |
| Open system; ineffective or no exposure controls                                                                                               | 4                              |

4. The ratings from Steps 1 through 3 were multiplied to obtain a job task exposure rating (Column J of Attachment 1-B). Based on the range of the result, an overall exposure rating was determined, as shown on Table 4 (Columns K and L of Attachment 1-B).

Table 4. Exposure rating system

| Multiplied <sup>†</sup> Total | Exposure Rating |
|-------------------------------|-----------------|
| <10                           | 0               |
| 10–20                         | 1               |
| 21–30                         | 2               |
| 31–40                         | 3               |
| >40                           | 4               |

<sup>†</sup> The multiplied total of the job task frequency/duration rating, carcinogen dispersion rating, and the level of control rating.

5. The health effect rating was determined by the Globally Harmonized System (GHS) Health Hazard Category, typically found on an SDS. Carcinogens are assigned either a Category 1 or 2 depending on the weight/strength of evidence, as determined by an identifying authoritative body (United Nations, 2011). Whether a chemical was classified as a carcinogen was determined using Cal/OSHA's

Hazard Communication Standard, which compiles listings from the following sources:<sup>4</sup>

- National Toxicology Program (NTP), "Report on Carcinogens" (NTP, 2016)
- International Agency for Research on Cancer (IARC) "Monographs on the Evaluation of Carcinogenic Risks to Humans" (IARC, 2020)
- Substances subject to regulation under the Occupational Carcinogen Control Act or that are regulated in Title 8, Article 110, Regulated Carcinogens (§5209, Carcinogens)
- Substances that meet the definition of "select carcinogen" in Title 8, Section 5191
- Where OSHA has included cancer as a health hazard to be considered by classifiers for a chemical covered by 29 CFR part 1910, Subpart Z.

The GHS category was converted to a health effect rating, as shown on Table 5 (and in columns M and N of Attachment 1-B).

Table 5. Health effects rating

| GHS Health Hazard Category† | Health Effects Rating |  |
|-----------------------------|-----------------------|--|
| Category 2                  | 3                     |  |
| Category 1                  | 4                     |  |

<sup>†</sup> Carcinogens only.

6. The exposure rating from Step 4 and health effects rating from Step 5 were combined to yield an overall risk ranking, ranging from "trivial" to "very high." The risk ranking matrix is provided below in Table 6 (and in column O of Attachment 1-B).

Table 6. Risk ranking matrix

| Health           |         | Exposure Rating |          |      |           |
|------------------|---------|-----------------|----------|------|-----------|
| Effects Rating 0 | 1       | 2               | 3        | 4    |           |
| 4                | Trivial | Moderate        | Moderate | High | Very High |
| 3                | Trivial | Moderate        | Moderate | High | Very High |

# 4 Results

# 4.1 Determination of Representative Facilities

ToxStrategies corresponded by email and held two primary phone calls with AFSCME Local 119 representatives to determine which facilities would best represent the environment in which fire mechanics work. Specifically, we discussed the job titles of the personnel and the differences in the work tasks, as well as the physical locations where the fire mechanics work. Based on this information, ToxStrategies identified three main facilities of operation within the County of Los Angeles Fire Department as representative: the Eastern Fire Shop, the North County Fire Shop, and the Pacoima Air Operations/Breathing Apparatus (BA) Shop. Through interviews with mechanics and managers at these locations, we also recognized the category of field mechanics, who work across the county at local fire stations and at locations where fire equipment is dispatched, including wildfires. These mechanics do not work at the main facilities but have similar potential for exposure, because they contact the residue from fires that is on the surface of the apparatuses and equipment.

# 4.2 Determination of Similar Exposure Groups (SEGs)

The four fire mechanic classifications are (1) Equipment Maintenance Worker, (2) Fire Equipment Mechanic (FEM), (3) Helicopter Mechanic, and (4) Helicopter Maintenance Inspector. In fire mechanic classifications 1, 2, and 3, there is a further designation as either journey- or senior-level. The more experienced senior-level classification is the lead fire mechanic and typically performs more complicated tasks, and is responsible for providing technical guidance to the journey-level mechanics. However, we learned that journey- and senior-level mechanics have similar potential for exposure to carcinogens in the work environment. Approximately 72 mechanics are assigned to the Los Angeles Fire Department in the four classifications. Figure 1 presents the four fire mechanic classifications and their respective site locations. Of note, however, we recognize that there are other locations where fire mechanics work, including fire stations throughout the County, and these mechanics are designated as "field-assigned."

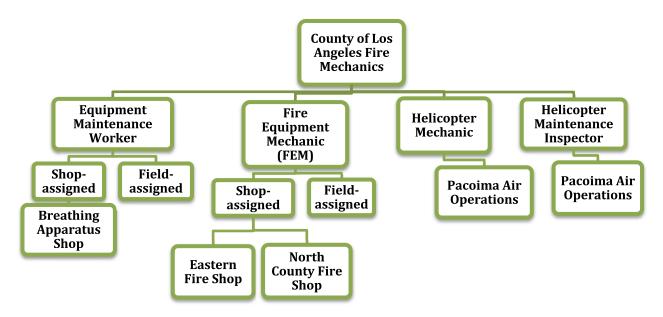

Figure 2. County of Los Angeles Fire Mechanics' four classifications and respective site locations

### 4.2.1 Equipment Maintenance Worker

The Equipment Maintenance Worker classification has a total of seven workers (six journey-level workers and one senior-level worker) with shop locations based in Pacoima (same site location as Pacoima Air Operations). Shifts are 40 hours per week, with overtime up to approximately 100 hours per year for each worker. Shop locations at Pacoima include the Breathing Apparatus (BA) Shop, Small Engine Repair Shop, and Fire Hose Repair Shop. These workers maintain and repair various types of equipment and tools at the Pacoima shops or in the field (other shop [Eastern Fire Shop or North County Fire Shop] or fire station locations). The Equipment Maintenance Workers will work in the field approximately 50% of their time, and any equipment that cannot be fixed in the field is sent to Pacoima.

Tasks include equipment examination and analysis of equipment malfunctions or mechanical failure. Other jobs include tuning up equipment used by the County fire stations, such as rescue tools, lawn mowers, vacuums, and generators, which can be performed in the Small Engine Repair Shop or in the field. Additionally, the workers are also responsible for repairing fire-truck hoses and completing the hose test, which takes place in the Fire Hose Repair Shop. Equipment such as firefighter BAs will typically be maintained and tested at the Pacoima BA Shop, while fit-testing of the BAs will typically be conducted at the fire station. BAs used during fire training in simulated structure burns, such as that conducted at the Los Angeles County Fire Department Fire Station 129 in Lancaster, California, are maintained at the BA Pacoima shop. These BAs reportedly offgas after use and appeared to have considerably more black fire residue than the BAs used by firefighters in the normal line of duty.

#### 4.2.2 Fire Equipment Mechanic (FEM)

Among the FEM classification, there are currently 48 mechanics, including eight at the senior level. The FEMs' shifts are 40 hours per week, plus overtime; typical overtime can sum to 200 hours over the course of one year for each FEM. Approximately half of the 48 mechanics are shop-assigned, and the other half are field-assigned: seven FEMs are assigned to the Lancaster Shop, 17 FEMs are assigned to the Eastern Shop, and 24 FEMs are assigned to the field. The mechanics that are shop-assigned work full time at either the Eastern Fire Shop or the North County Fire Shop. The field-assigned mechanics do not have an assigned work location, and their jobs can take place at any location, including a Los Angeles County fire station, wildfire base camp, roadside, or even at a fire site (known as the "red zone"). Because the field-assigned mechanics perform work wherever it is needed, they can spend a considerable amount of time in the car, driving to various locations.

Typically, field-assigned mechanics will work at a minimum of three fire stations but will have a base fire station where they conduct administrative tasks such as paperwork. Field duties typically include relatively minor repairs and service-scheduled items such as work on lights, sirens, batteries, and tires. However, based on personnel interviews, we understand that, recently, field-assigned mechanics have been assigned more major repairs, such as leaf spring changes, small transmission changes, fabrication of plumbing for pumps and supported equipment, seat change-outs, fluid changes, and water plumbing valve change-outs. Shop-assigned FEMs typically work on the major repairs such as engine and transmission changes, in-frame engine rebuilds, differential exchanges and rebuilds, major pump repair, plumbing issues, and water tank removal, and they are required to do more welding for significant parts repair and replacement. Additionally, field-assigned mechanics and shop-assigned mechanics have mandatory after-hours shifts throughout the year in which the field-assigned mechanic is the primary on-call mechanic and the shop-assigned mechanic is the backup.

The FEMs are responsible for the County-owned fleet from 175 fire stations/22 Battalions. The fleet consists of 217 total Engine Companies (Type I, Type III, and Type VI), 33 Truck Companies (Light Forces and Quints), 112 Paramedic Units (Air Squads, Assessment Engines, Assessment Quint/Light Force, Engines, and Squads), as well as reserve equipment (58 Engines, 10 Trucks/Quints, 31 Squads, and 21 Battalion SUVs).

#### 4.2.3 Helicopter Mechanic

There are fifteen Helicopter Mechanics, including three at the senior level, who are based out of Pacoima Air Operations. All the Helicopter Mechanics are required to have an airframe and power plant mechanic's certificate issued by the Federal Aviation Administration (FAA). Their shifts are typically 9-hour days with one day off every other week (9/80) plus overtime up to 500 hours per year per mechanic. Similar to the FEM, there may be required 24-hour shifts where the mechanic is on call during that time. Their job role consists of mechanical maintenance, repairs, and alterations to airframes, engines, and other components of helicopters owned and operated by the County. Heavier maintenance includes disassembling and reassembling airframes, engines, and other components and parts. Routine daily inspection and maintenance typically takes place

outdoors on the flight line or in a covered area off the flight line, while major helicopter repairs take place inside the hangar.

A Helicopter Mechanic may need to travel about once per month to the North County Fire Shop, because that site has a helicopter landing area. Otherwise, all maintenance and repairs are performed at Pacoima Air Operations. The Helicopter Mechanics are responsible for ten County-owned helicopters (five Bell 412s and five Firehawks).

## 4.2.4 Helicopter Maintenance Inspector

At Pacoima Air Operations, two Helicopter Maintenance Inspectors, with an Inspection Authorized Certificate issued by the FAA, work with the Helicopter Mechanics and perform all the inspections of completed repairs and alterations to ensure compliance with manufacturer's directives and federal regulations. About 60% of a Helicopter Maintenance Inspector's time is spent inspecting completed repairs and alterations, which may include airframes, power plant, propeller, or appliance, on both reciprocating and turbine-powered helicopters. The balance of their time is spent completing administrative tasks, such as ensuring that FAA-required reports and maintenance records are complete and in compliance with directives. Helicopter Maintenance Inspectors have a schedule similar to the Helicopter Mechanics (9/80) but may have more overtime hours than a helicopter mechanic (up to 650 hours per inspector per year). In addition, due to his specialty, one of the Helicopter Inspectors does most of the aircraft painting at the Pacoima Air Operations.

# 4.3 Exposure Ranking for Each SEG to Carcinogens

An overall risk ranking was calculated for each job task, for each SEG, as described in Section 3.3. The job task rating results are provided in Attachment 1-B, along with the Qualitative Summary in Attachment 1-A.

#### 4.3.1 Equipment Maintenance Worker

The overall qualitative risk ranking for the Equipment Maintenance Worker ranged from "trivial" to "high." The highest risk ranking for the Equipment Maintenance Worker was the job task of repair and tune-up of power equipment and rescue tools in the Engine Repair Shop. During the site visit on September 16, ToxStrategies observed strong gasoline odors when entering this shop location. According to communication with the Senior Equipment Maintenance Worker, Mr. Snyder, one Equipment Maintenance Worker works at this location full time, and three other Equipment Maintenance Workers work there part time. Personal protective equipment (PPE) includes latex gloves and an apron. There is one door that provides ventilation in this shop, but we were told that future plans include installing additional ventilation. Based on SDS review, the gasoline used for the various power equipment stored in the Engine Repair Shop is expected to contain three carcinogens—benzene, ethylbenzene, and naphthalene—and if the engines are run in the shop, this worker would also be exposed to gasoline engine exhaust.

The fire hose repair had an overall risk ranking of "moderate" based on the potential for off-gassing of fire-related fumes and the potential presence of soot, which is considered carcinogenic, as well as other unknown contaminants. One Equipment Maintenance

Worker works at the Fire Hose Repair Shop part time (>4 hours per day). The Fire Hose Repair Shop has a front door and additional roll-up doors that stay open during warmweather months. Personal protective equipment (PPE) includes latex gloves and an apron.

Equipment Maintenance Workers infrequently have to spray-paint equipment at their shops. PPE includes latex gloves and an apron. Based on review of the SDSs, the spray paints used by the workers may contain up to three carcinogens, depending on the specific product used. The carcinogens identified in the evaluated products are ethylbenzene, carbon black, and titanium dioxide. It should be noted that carbon black and titanium dioxide are considered carcinogenic only if they are "airborne, unbound particles of respirable size." Given the presence of these substances in a paint matrix, neither carbon black nor titanium dioxide would be present as unbound particles. Additionally, carbon black and titanium dioxide have been shown to be carcinogenic in the lung only in rodent bioassays and by a mechanism of pulmonary insoluble particulate overload, which is highly unlikely from occasional use of spray paint (IARC, 2010a). Based on the short task duration (approximately 30 minutes) and the low frequency of the task (three to five times per month), the overall risk ranking for spray painting was "trivial."

Table 7 includes the list the carcinogens identified as a potential exposure concern for the Equipment Maintenance Worker.

Table 7. Carcinogenic chemicals of potential concern (COPCs) identified in the Equipment Maintenance Worker

| Carcinogen Identified in Exposure Studies | Identifying Authoritative Body |
|-------------------------------------------|--------------------------------|
| Carbon black                              | IARC-2B                        |
| Titanium dioxide                          | IARC-2B                        |
| Engine exhaust, gasoline                  | IARC-2B                        |
| Benzene                                   | NTP-K, IARC-1, OSHA 1910.1028  |
| Soot                                      | NTP-K; IARC-1                  |
| Ethylbenzene                              | IARC-2B                        |
| Naphthalene                               | NTP-R, IARC-2B                 |

Abbreviations: NTP = National Toxicology Program; NTP-K = known to be human carcinogens; NTP-R = reasonably anticipated to be human carcinogens; IARC = International Agency for Research on Cancer; IARC-1 = carcinogenic to humans; IARC-2B = possibly carcinogenic to humans; OSHA = Occupational Safety and Health Administration

#### 4.3.2 Fire Equipment Mechanic (FEM)

The overall qualitative risk ranking for the FEM ranged from "trivial" to "very high," as presented in Attachment 1.

As clarified by the California Office of Environmental Health Hazard Assessment.

The job task of repairing fire apparatus or other equipment at a wildfire base camp or fire site resulted in the "very high" risk ranking. Depending on the number of wildfires that occur each year, the field-assigned FEMs may get called to a wildfire base camp<sup>6</sup> for approximately 2-week durations, 24 hours per day. During this time, the assigned FEMs are required to stay onsite for the duration of the period and are responsible for repairing any fire apparatus or fire equipment that is needed. Further, field-assigned FEMs may also get called to a fire site. Although infrequent (occurring approximately once every three years), the field-assigned FEM is responsible for needed fire apparatus repairs anywhere, at any time. Therefore, there are no exposure bounds for this group of workers and the level of PPE provided (work boots, work uniform, gloves, eye protection, N95 respirator) is less than that provided to the firefighters. The carcinogenic exposures of this job task, not including any carcinogenic exposures from chemical products used for the repair work, include fire smoke in the air, off-gassing of fire-related fumes, soot/fire residue on the apparatus and equipment, and other unknown contaminants. IARC reported concentrations of chemicals during wildland firefighting operations to be acetaldehyde, benzene, formaldehyde, and particulate matter (IARC, 2010b). Based on the data gathered from the County, and on professional judgment, ethylbenzene, naphthalene, PAHs, and diesel exhaust are also likely carcinogens of concern.

The shop-assigned FEMs at either the Eastern Fire Shop or the North County Fire Shop have facilities with roll-up doors and a diesel exhaust capture system that can be used when the apparatus is running inside the building, but those systems are not operating when the vehicles are moving in and out of the Shop. The Eastern Fire Shop also has side wall vents that exhaust air out of the building. ToxStrategies applied minimal levels of control assumptions (e.g., open system; some degree of engineering controls) when assessing an overall risk ranking for the field-assigned FEM, because the field-assigned FEMs do not have a standard maintenance work area, and the controls can be variable.

The highest risk ranking for the shop-assigned FEM of "moderate" was for daily maintenance of the fire apparatus, which is a highly variable job task and encompasses a wide range of products and tools. FEMs may use a combination of a face shield, gloves (rubber or latex), N95 respirator, and work boots when performing their job task. The daily maintenance of the fire apparatus occurs during the entire day, every day. The chemical ingredients of each product's SDS were evaluated for carcinogenicity and were included in the overall risk ranking. The carcinogens identified in the evaluated products include titanium dioxide, cumene, gasoline, benzene, ethylbenzene, naphthalene, carbon black, methyl isobutyl ketone, formaldehyde, diethanolamine, tetrachloroethylene, and N,N-dimethyl-p-toluidine. As discussed above, carbon black and titanium dioxide are not present in a matrix that would classify them as carcinogenic.

As described in Section 4.2.1, the fire hose, as well as other components of the fire apparatus, can have the potential for off-gassing of fire-related fumes and the potential

The outdoor base camps are a mobilization and staging area for firefighters and support personnel during a large wildfire.

Particulate matter is not considered an occupational carcinogen and, thus, is not discussed further.

presence of soot and other unknown contaminants. Diesel exhaust can also be a potential source of exposure for the FEMs when the apparatus is running. Therefore, soot and diesel exhaust were also included in the carcinogen list for this job task.

The other three job tasks with carcinogenic exposure yielded an overall risk ranking of "trivial," driven by the task duration and low vapor pressures/dustiness factors of the identified carcinogenic chemicals. These job tasks were (1) light welding and fabrication for the fire apparatus, (2) painting of fire apparatus components, and (3) wrapping the exhaust of the fire apparatus with vermiculite-coated fiberglass strips.

Light welding of sheet metal (stainless steel and aluminum) by shop-assigned FEMs may occur once per month for a maximum of one hour. PPE includes a welding helmet, welding gloves, and an N95 respirator. Carcinogens in welding fumes have the potential to be an exposure concern among FEMs, although, based on the short task duration and frequency, this job task resulted in a "trivial" risk rating.

Painting of fire apparatus components by the shop- or field-assigned FEMs takes place twice per month for a maximum of one hour total. PPE includes latex gloves, eye protection, and an N95 respirator. The potential carcinogens of concern identified in painting include titanium dioxide and methyl isobutyl ketone. However, as discussed above, titanium dioxide is not present in a matrix that is considered carcinogenic.

The job task of wrapping the exhaust of a fire apparatus with vermiculite-coated fiberglass strips may take up to one hour and may be performed every two weeks. The shop- or field-assigned FEM's PPE includes goggles (or other eye protection), latex gloves, and knee pads. Historically, vermiculite had the potential to contain traces of asbestos, which is a carcinogen. It is uncertain whether the vermiculite found in the currently used fiberglass strips contains trace asbestos and whether it is a potential exposure concern for the FEMs. Therefore, for the purposes of this risk ranking, it was conservatively assumed that the vermiculite-coated fiberglass strips used historically, and perhaps even the strips in current usage, contain trace asbestos. However, given the low dustiness of the fiberglass strips and the minimal duration and frequency of usage, this job task's overall risk ranking is considered "trivial."

Finally, exposure risk that was identified through the site visit and personnel interviews but was not attributable to use of a specific product includes the potential for exposure to diesel exhaust when the apparatuses enter or exit the shop, unknown potential for exposure to chemicals in the soot that exists on the equipment (e.g., hoses, ladders), off-gas from fire-contaminated equipment, and unknown contaminants on the underside and inside the mechanical compartments of the apparatus. As discussed above, field-assigned FEMs may be exposed to smoke at a fire, either by working at the wildfire base camp or at an actual fire.

Table 8 lists the carcinogens identified as potential exposure concerns for the FEM (shop-and field-assigned).

Table 8. Carcinogenic chemicals of potential concern (COPCs) identified in the FEM (shop- and field-assigned)

| Carcinogen Identified in Exposure Studies                                                                                                                                           | Identifying Authoritative Body                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Carbon black                                                                                                                                                                        | IARC-2B                                                                        |
| Cumene                                                                                                                                                                              | NTP-R, IARC-2B                                                                 |
| Titanium dioxide                                                                                                                                                                    | IARC-2B                                                                        |
| Engine exhaust, gasoline                                                                                                                                                            | IARC-2B                                                                        |
| Engine exhaust, diesel                                                                                                                                                              | NTP-R, IARC-1                                                                  |

| Soot                                                                                                                                                                                | NTP-K; IARC-1                                                                  |
| Polycyclic aromatic hydrocarbons (PAHs) (Benzo[a]anthracene, Benzo[a]pyrene, Benzo[b]fluoranthene, Benzo[k]fluoranthene, Chrysene, Dibenzo[a,h]anthracene, Indeno[1,2,3-c,d]pyrene) | NTP-R, IARC (1, 2A, or 2B) [classification dependent on specific PAH compound] |
| Ethylbenzene                                                                                                                                                                        | IARC-2B                                                                        |
| Naphthalene                                                                                                                                                                         | NTP-R, IARC-2B                                                                 |
| Methyl isobutyl ketone                                                                                                                                                              | IARC-2B                                                                        |
| Formaldehyde                                                                                                                                                                        | NTP-K, IARC-1, OSHA 1910.1048                                                  |
| Diethanolamine                                                                                                                                                                      | IARC-2B                                                                        |
| Tetrachloroethylene                                                                                                                                                                 | NTP-R, IARC-2A                                                                 |
| N,N-dimethyl-p-toluidine                                                                                                                                                            | IARC-2B                                                                        |
| Welding fumes                                                                                                                                                                       | IARC-1                                                                         |
| Asbestos                                                                                                                                                                            | NTP-K, IARC-1, OSHA 1910.1001                                                  |

Abbreviations: NTP = National Toxicology Program; NTP-K = known to be human carcinogens; NTP-R = reasonably anticipated to be human carcinogens; IARC = International Agency for Research on Cancer; IARC-1 = carcinogenic to humans; IARC-2A = probably carcinogenic to humans; IARC-2B = possibly carcinogenic to humans; OSHA = Occupational Safety and Health Administration

#### 4.3.3 Helicopter Mechanic / Helicopter Maintenance Inspector

The overall relative risk ranking for the Helicopter Mechanic and Helicopter Maintenance Inspector ranged from "trivial" to "very high." The highest risk ranking out of the identified job tasks for the Helicopter Mechanic was the heavy maintenance work on the aircraft, which yielded a ranking of "very high." Heavy maintenance of the aircraft typically takes place inside the hangar, and the mechanics generally wear a uniform, work boots, goggles/safety glasses, hearing protection, gloves (type dependent on task), and knee pads. The carcinogens of potential exposure include hexavalent chromium and crystalline silica. Hexavalent chromium dust/powder is reported to exist on the hot side of the engine. It was recently announced (July 2020) that hexavalent chromium could be present on the engine

and that the engine should not be cleaned by blowing air on to the surface. Prior to the announcement, the Helicopter Mechanic did not take special handling precautions when working with this piece of the engine. Therefore, exposure to hexavalent chromium during engine maintenance and repair may have been higher in the past. Based on the regularly scheduled service of the helicopters, it is very likely that the mechanic could routinely contact the dust on the engine, which might contain hexavalent chromium residues on a regular basis.

An additional exposure concern during the heavy maintenance work on the aircraft includes the talcum (talc) powder used on the surface of the fuel cells. The helicopter mechanics use the talc powder as an "anti-chaff" barrier between the rubber components and metal, such as in the case of the fuel cells. Talc is applied to a surface area of approximately 50 square feet, and based on the regularly scheduled service of the helicopters, the mechanics are exposed to fuel cells for approximately eight months of the year. Historically, talc contained the carcinogen asbestos, but asbestos has since been phased out. Currently, talc is known to contain 0.1% to 1% quartz, which is an exposure concern for the carcinogen, crystalline silica, but the percent composition is low.

A second opportunity for exposure to the talc powder on the fuel cells is when the mechanic has to check for oil leaks in the engine compartment, which requires the mechanic to crawl inside the aircraft's compartments where the deposited talc may be disturbed and become airborne in the confined area where air may be stagnant. This task occurs at a frequency of one hour (maximum), every three weeks. The PPE generally worn by the mechanic includes work boots, work uniform, and latex gloves. This job task yielded a risk ranking of "high," based on the potential for exposure to crystalline silica in the talc.

Several job tasks of the Helicopter Mechanic yielded a risk ranking of "moderate." These include the following: intermediate maintenance on the aircraft, painting/priming the interior/exterior of the aircraft, sanding and painting helicopter blades, and painting using aerosol paints and/or epoxy primers.

Intermediate maintenance on the aircraft takes place on a daily basis and can take approximately an hour to complete. This job is usually conducted outdoors on the flight line, and PPE includes work boots, work uniform, goggles/safety glasses, hearing protection, gloves (dependent on task), and knee pads. During the intermediate maintenance, a mechanic may potentially be exposed to carcinogens present in the various products used (e.g., Mastinox, Jet A fuel, Gunk Carburetor Cleaner, Bonderite Maintenance Cleaner), and could also be exposed to carcinogenic exhaust fumes and residues such as Jet A fuel exhaust and hexavalent chromium powder on the aircraft engine (discussed above). Soot and other residues are likely present on the aircraft exterior, especially during wildfire season, which can create an exposure concern for the helicopter mechanic. The carcinogenic chemicals of concern for this job task include hexavalent chromium, naphthalene, benzene, ethylbenzene, diethanolamine, and soot.

Painting, priming, and sanding of aircraft components can take place in the paint booth, inside the hangar, or outside in the open air, depending on the aircraft component. The mechanic may use a variety of different paints, paint strippers, primers, and enamels that

contain the carcinogens methylene chloride, hexavalent chromium, carbon black, titanium dioxide, 4-chlorobenzotrifluoride, and ethylbenzene. Depending on the paint job, it could take 30 minutes or less and be performed once per week, or it could take 10 hours a week and be performed for 40 hours a month. For the major paint jobs, the Helicopter Maintenance Inspector is the primary painter. His work typically takes place in the paint booth, with installed exhaust filters, with the use of an airline respirator.

Other tasks that mechanics perform that ranked as "trivial" include metal etching of small components and metal grinding on stainless steel, aluminum, or titanium metal parts. Metal etching requires the use of Alodine, which contains the carcinogen hexavalent chromium. Hexavalent chromium is a respiratory carcinogen, and there is very limited opportunity for it to be airborne as a result of the use of Alodine in this process. This task typically takes place in the Composite/Sheet Metal Room inside the hangar, or could take place on the aircraft itself. The job task frequency and duration is approximately 30 minutes, every three days. PPE generally worn for this task includes work boots, work uniform, and latex gloves. Metal grinding is also considered a low-frequency and low-duration task, because it typically takes five minutes to complete on a daily basis. PPE includes work boots, work uniform, latex gloves, hearing protection, and an N95 respirator. The metal grinding may produce dust that contains carcinogens, including hexavalent chromium, nickel, and titanium dioxide; however, these exposures are expected to be of low concentration and infrequent.

Finally, exposures to carcinogens that were identified through the site visit and personnel interviews, but were not attributable to use of a specific product, include helicopter engine exhaust (Jet A fuel exhaust), unknown chemicals in the soot residue, and off-gassing volatile chemicals from wildfire residuals on the equipment and surface of the aircraft. One helicopter mechanic stated during the site visit that the indoor hangar frequently gets filled with helicopter exhaust during landing and takeoff, due to its proximity to the helipad. All helicopters return to Air Operations each day for their 24-hour inspection; therefore, the Helicopter Mechanic (or Helicopter Maintenance Inspector) has frequent opportunities to be exposed to these contaminants, because they have to climb onto the aircraft at various locations and inspect exterior surfaces, usually without the use of PPE.

Table 9 includes the list of carcinogens identified as potential exposure concerns for the Helicopter Mechanics and Helicopter Maintenance Inspectors.

Table 9. Carcinogenic chemicals of potential concern (COPCs) identified in the Helicopter Mechanics and Helicopter Maintenance Inspectors

| Carcinogen Identified in Exposure Studies | Identifying Authoritative Body |
|-------------------------------------------|--------------------------------|
| Hexavalent chromium                       | NTP-K, IARC-1                  |
| Naphthalene                               | NTP-R, IARC-2B                 |
| Benzene                                   | NTP-K, IARC-1, OSHA 1910.1028  |
| Ethylbenzene                              | IARC-2B                        |
| Diethanolamine                            | IARC-2B                        |
| Methylene chloride                        | NTP-R, IARC-2A, OSHA 1910.1052 |
| Tetrahydrofuran                           | IARC-2B                        |
| Crystalline silica                        | NTP-K, IARC-1, OSHA 1910.1053  |
| 4-Chlorobenzotrifluoride                  | IARC-2B                        |
| Carbon black                              | IARC-2B                        |
| Soot                                      | NTP-K, IARC-1                  |

Abbreviations: NTP = National Toxicology Program; NTP-K = known to be human carcinogens; NTP-R = reasonably anticipated to be human carcinogens; IARC = International Agency for Research on Cancer; IARC-1 = carcinogenic to humans; IARC-2A = probably carcinogenic to humans; IARC-2B = possibly carcinogenic to humans; OSHA = Occupational Safety and Health Administration

# 5 Conclusions

The qualitative assessment identified four SEGs: (1) Equipment Maintenance Worker, (2) Fire Equipment Mechanic (FEM), (3) Helicopter Mechanic, and (4) Helicopter Maintenance Inspector. Several carcinogenic chemicals were identified in the products used by the various SEGs, and in the vehicle and aircraft exhaust emissions. Additionally, findings from Task 1, Structured Literature Review, indicated that PAHs in surface dust at fire stations and diesel emissions in fire-station vehicle bays could be elevated (Shen et al., 2012, 2015, Chung et al., 2020, Sparer et al., 2017, Echt et al., 1995, Froines et al., 1987) and off-gassing of benzene, ethylbenzene, 1,4-dichlorobenzene, and styrene have been measured in PPE that had been exposed to a fire (Fent et al., 2015). Finally, firefighter industrial hygiene samples collected during wildland firefighting demonstrated potential for low-level exposures to carcinogens such as crystalline silica, acetaldehyde, formaldehyde, PAHs, and benzene (Materna et al., 1992). Therefore, carcinogens may be present in the surface residuals on various fire equipment vehicles, PPE, and the surfaces of the shops themselves, as well as in the field when working near or at a wildland fire.

To determine whether the theoretical cancer health risk is elevated among this group of workers, the magnitude of the fire mechanics' exposures must be determined. This qualitative exposure assessment was the first step in characterizing the potential exposures. Based on the outcome of the risk ranking, ToxStrategies recommends conducting quantitative exposure assessments (i.e., measurements) of crystalline silica and hexavalent

chromium in personal breathing zone (pbz) air samples of the Helicopter Mechanics when (1) conducting heavy maintenance on the aircraft and (2) checking for oil leaks, which tasks received overall risk rankings of "very high" and "high," respectively. When the helicopter mechanics perform intermediate daily aircraft maintenance, ToxStrategies plans to collect pbz air samples to be analyzed for hexavalent chromium, naphthalene, benzene, and ethylbenzene. Although diethanolamine and tetrahydrofuran were also considered potential carcinogens of concern for this job task, these compounds will not be measured quantitatively, because they do not have published cancer potency measures. Thus, the cancer risk assessments for these chemicals will be qualitative. In addition to pbz air samples, surface samples will also be collected and analyzed for soot compounds for all three helicopter mechanic job tasks described above, as well as hexavalent chromium, when conducting intermediate daily aircraft maintenance.

For the Helicopter Mechanic/Helicopter Maintenance Inspector job tasks of (1) painting/priming on the interior and exterior of the aircraft, (2) sanding helicopter blades, (3) painting helicopter blades, and (4) painting using aerosol paints and epoxy primers, ToxStrategies plans to collect pbz air samples to be analyzed for hexavalent chromium, methylene chloride, 4-chlorobenzotrifluoride, and ethylbenzene. In addition to pbz samples, surface samples will also be collected during painting/priming on the interior and exterior of the aircraft and analyzed for hexavalent chromium. These four job tasks received an overall risk ranking of "moderate."

At the Engine Repair Shop located at the Breathing Apparatus Shop location, ToxStrategies plans to measure naphthalene, benzene, and ethylbenzene through pbz air samples, and soot compounds through surface samples. The Engine Repair Shop is where the equipment maintenance workers repair and tune up power equipment and rescue tools (e.g., weed trimmers, generators, and vacuums). This job task received an overall risk ranking of "high."

The Fire Hose Shop is also located at the Breathing Apparatus Shop location and is where the workers repair and complete the firefighting hose test. This job task received an overall risk ranking of "moderate." The plan is to collect surface samples at the Fire Hose Shop to be analyzed for soot compounds.

When the shop-assigned Fire Equipment Mechanic conducts general maintenance of the fire apparatus (overall risk ranking of "moderate"), ToxStrategies plans to collect pbz air samples of benzene, ethylbenzene, naphthalene, N,N-dimethyl-para-toluidine, tetrachloroethylene, diesel exhaust particulates, and welding fumes. Cumene and methyl isobutyl ketone were also considered potential carcinogens of concern for this job task; however, these compounds will not be measured quantitatively, because they do not have published cancer potency measures. Thus, their cancer risk assessment will be qualitative only. Surface samples will be collected and analyzed for soot compounds, and a bulk sample of the vermiculite-coated fiberglass strips will be analyzed for asbestos.

If possible, ToxStrategies also plans to collect pbz air samples from the field-assigned Fire Equipment Mechanics at a wildfire base camp, measuring acetaldehyde, benzene, ethylbenzene, formaldehyde, PAHs, naphthalene, and diesel exhaust particulates. Surface

samples will also be collected and analyzed for soot compounds. This job task received an overall risk ranking of "very high."

Table 10 is a summary of the measurement strategy for use in quantifying exposures incurred by the Fire Mechanics. As shown, the strategy includes measurements of air concentrations and surface levels of the identified carcinogens.

Table 10. Quantitative assessment strategy by SEG and job task

# 6 Next Steps

Task 4 will use the results of this study (Task 2) to conduct exposure monitoring of workers for airborne chemicals, as well as chemical analysis of surface residues, as summarized in Section 5 above. Samples from each SEG will be selected for personal breathing-zone air sampling and surface/dermal wipe sampling of equipment. Due to limitations of budget and schedule, sampling will focus on collecting data for the highest ranking possible exposure conditions.

Task 5 will use the results of Task 4 and will include calculating the theoretical excess cancer risk from exposure to carcinogenic materials for each SEG determined from Task 2 and toxicity criteria relevant for California risk assessments. The risk assessment will result in an estimate of the probability of developing cancer as a result of exposure, expressed in terms of the numbers of people out of one million. Varying degrees of conservatism will be added to this approach to ensure that cancer risk is not underestimated, which makes it probable that potential risk will be overestimated.

For Task 3, Epidemiologic assessment, employee records are being evaluated for completeness and suitability for a future cancer epidemiologic study.

Task 6 may include analyzing public comments, explaining the rationale for specific policy recommendations, and disseminating the study findings to the governor, state legislature, Occupational Safety and Health Standards Board, Los Angeles County Board of Supervisors, and stakeholders in the workers' compensation system.

# 1 Background and Rationale

The International Agency for Research on Cancer (IARC) and recent epidemiologic studies have suggested that firefighters may be at increased risk for certain cancers due to their occupational exposures to carcinogens found in fire gases and smoke (e.g., benzene, polycyclic aromatic hydrocarbons [PAHs], cadmium, crystalline silica), as well as exposures to other agents (e.g., diesel exhaust) (IARC, 2010; LeMasters et al., 2006; Tsai et al., 2015). Since January 1, 2012, firefighters have been included in the California Cancer Presumption for worker compensation purposes (California Labor Code §3212.1). With these benefits, a firefighter who develops cancer can be awarded compensation for medical treatment and disability benefits, if the individual demonstrates that he or she was exposed to a carcinogen during the course of their employment. In comparison, mechanics who repair and clean firefighting vehicles and equipment are not covered by this worker compensation program. Repairing and cleaning firefighting vehicles and equipment (trucks, helicopters, axes, hoses, etc.) at a fire station or offsite at a fire event may expose the mechanics to fire-related carcinogens, similar to those experienced by the firefighters.

As a result, California Assembly Bill (AB) 1400 was created to define the fire mechanic's risk of exposures to carcinogens in the course of employment (AB 1400, 2019). Specifically, AB 1400, Section 77.7, was added to the Labor Code on October 11, 2019, and requires the Commission on Health and Safety and Workers' Compensation (CHSWC), in partnership with the County of Los Angeles (LA County) and relevant labor organizations, to submit a study to the Legislature, the Occupational Safety and Health Standards Board, and the Los Angeles County Board of Supervisors "on the risk of exposure to carcinogenic materials and incidence of occupational cancer in mechanics who repair and clean firefighting vehicles" (Labor Code, 2019). The study components include:

- Site visits at representative facilities in Los Angeles County, California
- Interviews and surveys with current and former fire mechanics to assess potential exposures to carcinogens
- Occupational exposure measurements of carcinogens identified as potentially present in the workplace, to evaluate potential exposure to carcinogens
- Quantitative health risk assessment of potential increased cancer risk associated with exposure to carcinogens in the workplace.

ToxStrategies was contracted by the California Department of Industrial Relations (DIR), CHSWC, to conduct the study as outlined in AB 1400. ToxStrategies' approach to address these study components includes six tasks:

- Task 1: Structured Literature Review summary of available scientific literature on exposure to chemical carcinogens and studies of cancer risk among fire mechanics
- Task 2: Qualitative Exposure Assessment site visits at representative facilities

- Task 3: Epidemiologic assessment feasibility study of cohort enumeration
- Task 4: Quantitative Exposure Assessment measurement of current occupational exposures to carcinogens
- Task 5: Cancer risk assessment calculation of theoretical excess cancer risks from occupational exposure to carcinogens
- Task 6: Technical assistance to the DIR.

The purpose of Task 3 (epidemiologic assessment) is to determine the feasibility of conducting an epidemiology study to assess the risk of cancer in fire mechanics. A feasibility study helps to determine whether a full epidemiologic study is warranted based on availability of data and potential number of participants. Conducting an epidemiologic study without this first step would likely waste limited resources and may not provide meaningful results. This report summarizes the objectives, methods, and results of the epidemiologic feasibility study and discusses recommendations for next steps.

# 2 Objectives

The objectives of Task 3 were as follows:

- 1. Evaluate employee records for completeness and suitability for a cancer study.
- 2. Ascertain availability of information in employee records for assessing disease confounders (e.g., smoking).
- 3. Develop recommendation for the appropriate epidemiology design.

# 3 Methods

Evaluating a potential risk of cancer for a specific occupation is most commonly conducted using a cohort study, which is an epidemiologic study design in which populations are assembled based on a common factor (e.g., employment as a fire mechanic), observed over time, evaluated for risk factors, and followed for a particular outcome. Cohort studies can be either prospective, where exposure to risk factors is evaluated as part of the study, and participants are followed forward in time, or retrospective, where exposures occurring in the past are used to define cohorts, and the outcomes have already occurred.

To assess the feasibility of assembling a retrospective cohort of fire mechanics in LA County to evaluate the risk of cancer, the following steps were taken:

- 1. Determine that occupation as an LA County fire mechanic can be ascertained and verified, typically through employment records (*exposure verification*).
- 2. Ensure that the outcome of cancer can be ascertained and verified through a relevant cancer registry or medical records that can be linked to cohort participants (*outcome ascertainment*).

- 3. Evaluate the size of the potential cohort by determining the number of people who ever held the occupation of interest (fire mechanics) during a specific timeframe (*cohort enumeration*).
- 4. Determine the availability of demographic and socioeconomic characteristics and medical history factors that may confound the relationship between occupation and cancer (*confounding variables*).

If a retrospective cohort of fire mechanics can be assembled and tracked for cancer outcomes, the incidence or mortality rates for certain cancers can be calculated within the cohorts and subsequently compared to the cancer rates of a comparable population to determine whether this occupation has higher (or lower) than expected rates of cancer.

ToxStrategies evaluated the feasibility of constructing a cohort of fire mechanics at LA County Fire and following them for cancer outcomes. ToxStrategies first conducted qualitative interviews with relevant LA County Fire personnel, including three fire equipment mechanics, the president of the American Federation of State, County and Municipal Employees (AFSCME) union local 119, and a representative from LA County Fire human resources (HR), to gauge the scope of available information needed for cohort assembly (Table 1). During the interviews, ToxStrategies staff members inquired as to the type of information captured in employee records, including personal identifying information and variables that may potentially confound the relationship between occupation and cancer, such as smoking and body mass index (BMI).

**Table 1.** Description of qualitative interviews

| Interviewee          | Position                                                     | Date of Interview |  |  |
|----------------------|--------------------------------------------------------------|-------------------|--|--|
| Luis del Cid         | Fire equipment mechanic                                      | 9/24/2020         |  |  |
| Grant "Sonny" DeRose | Fire equipment mechanic                                      | 9/24/2020         |  |  |
| Harry Wong           | Fire equipment mechanic                                      | 9/24/2020         |  |  |
| Gary Hodge           | President of the AFSCME union local; fire equipment mechanic | 9/29/2020         |  |  |
| Julia Kim            | LA County Fire HR Chief Risk Manager                         | 10/15/2020        |  |  |

After the interviews were completed, ToxStrategies worked with LA County Fire HR to obtain additional information needed for the feasibility study. Notably, the HR department was initially difficult to reach, and responses were often delayed for weeks due to the COVID-19 pandemic. On December 14, 2020, a letter was sent to the department on behalf of ToxStrategies from Assemblywoman Sydney Kamlager's office, one of the co-sponsors of the AB 1400 bill, to encourage response. If an epidemiologic study is pursued, a point person at the County HR will need to be identified to ensure timely response and

participation as the County HR keeps the records necessary to conduct the study for LA County fire mechanics.

#### 4 Results

## 4.1 Exposure Verification

LA County Fire employees are categorized by occupation using job classification codes. During one of ToxStrategies' site visits to LA County Fire, ToxStrategies was provided with a list of job classification codes for employees who would be considered fire mechanics, including equipment maintenance workers, fire equipment mechanics, helicopter mechanics, and helicopter maintenance inspectors (Table 2). Employees working in senior positions for these job titles conduct the same work as non-senior employees but they perform additional supervisory roles. All employees ever holding one of these job classification codes would be considered as part of the fire mechanic cohort.

Table 2. Job classification codes of fire mechanics

| Job Classification Code | Description                         |
|-------------------------|-------------------------------------|
| 6610                    | Equipment Maintenance Worker        |
| 7472                    | Fire Equipment Mechanic             |
| 7492                    | Helicopter Mechanic                 |
| 7496                    | Helicopter Maintenance Inspector    |
| 6613                    | Senior Equipment Maintenance Worker |
| 7473                    | Senior Fire Equipment Mechanic      |
| 7494                    | Senior Helicopter Mechanic          |

The job classification codes are included in various types of county records, including time sheets, personnel files, and union records. Each of these records could serve as a source for identifying participants in the cohort of fire mechanics, as well as determining the length of time employees held a particular position. LA County Fire keeps physical, original copies of official personnel files, as well as electronic records in the eHR system, a county-wide system of electronic personnel records. While personnel records are retained at the County for only five years after an employee's termination (voluntary or involuntary), a listing of employees by job classification code is available through the eHR system, which began in 2012, and the County-Wide Timekeeping and Payroll/Personnel System (CWTAPPS) system, which holds records from 1975 through 2012.

#### 4.2 Outcome Ascertainment

The California Cancer Registry (CCR) is a comprehensive statewide cancer surveillance program that captures diagnoses of cancer in the state of California since 1988. Cancer reporting is required by state law. Approximately 5.8 million cancer cases are available for research in the CCR, and nearly 200,000 additional cases are added annually. The CCR has achieved gold certification from the North American Association of Central Cancer Registries, the highest achievable standard, requiring case ascertainment of ≥95% completeness (California Cancer Registry, 2018).

The LA County Cancer Surveillance Program, which reports data to the CCR, has population-based cancer data available beginning in 1972 (USC, 2020) Cancer cases that occurred in LA County specifically could be traced back to 1972, while cases occurring outside the county could be traced back to 1988.

Cancer mortality can be evaluated using the National Death Index (NDI), a comprehensive database of all deaths occurring in the US from 1979 through 2019 (latest available data). Multiple causes of death are recorded in NDI records, and deaths due to cancer can be identified (CDC, 2021).

Employees at LA County Fire can be linked to the CCR and/or the NDI using their social security number and/or their date of birth, both of which are available in employee official personnel files, as well as through the eHR system. Thus, fire mechanics can be tracked reliably for cancer diagnoses and/or cancer-related death, provided that the cancer was diagnosed within the state of California. Because social security number and date of birth are sensitive personal identifying information, any epidemiologic study would require an ethical evaluation and approval from an institutional review board (IRB). A project proposal would need to be approved by the CCR to receive individual-level data.

#### 4.3 Cohort Enumeration

Using the CWTAPPS system (1975–2012 personnel records), as well as the eHR records (2012–2021), LA County Fire HR was able to provide the number of employees at LA County Fire who held the position of fire mechanic from September 1, 1975, through January 2021 (Table 3). September 1, 1975 was the earliest date available in the CWTAPPS system in order to identify employees holding one of these codes. Senior positions are often promoted internally, such that a single employee can have multiple job codes of interest. After removing duplicate listings of employees holding multiple job codes, a total of 180 individual employees were identified as having one of the fire mechanic classification codes. This is a preliminary estimate; employees holding the position for a short period of time (e.g., <90 days) may not be eligible for inclusion in the cohort.

Table 3. Number of LA County fire mechanics, 1975–2021

| Job Classification Code | Description                                                                                   | Number of Employees |
|-------------------------|-----------------------------------------------------------------------------------------------|---------------------|
| 6610, 6613              | Equipment Maintenance Worker, including promotion to Senior position                          | 20                  |
| 7472, 7473              | Fire Equipment Mechanic, including promotion to Senior position                               | 126                 |
| 7492, 7494, 7496        | Helicopter Mechanic, including promotion to Senior position; Helicopter Maintenance Inspector | 34                  |
|                         | Total                                                                                         | 180                 |

# 4.4 Confounding Variables

Prior to beginning employment at LA County Fire, fire equipment mechanics, equipment maintenance workers, helicopter mechanics and helicopter maintenance inspectors must complete a medical clearance evaluation. Employees undergo a physical evaluation at a separate occupational health clinic. These records are not typically included in employee personnel files, but they could potentially be obtained through the clinic. It is likely that potential confounding variables would be captured during the pre-employment physical, including smoking history, alcohol consumption, BMI, and personal and family medical history.

Confounding variables are also available from linkage with the California Cancer Registry, including tobacco use, comorbidities, patient height and weight, race, and socioeconomic indicators. While some of these variables have been evaluated since the registry's inception in 1988 (comorbidities, race, socioeconomic variables), others are available only for cases diagnosed in 2011 and later (height, weight, tobacco use). Thus, these variables can be used only to validate available data from the pre-employment physical records. Additionally, age, sex, and race may be available using the National Death Index.

# 4.5 Potential Comparison Populations

As a first step, the cancer incidence rates in the fire mechanic cohort could be compared to the age- and sex-standardized cancer incidence and/or mortality rates in the state of California. An incidence rate is calculated by taking the number of newly diagnosed cancer cases over a period of time and dividing by the at-risk population during that time frame. This is usually calculated as a rate per person-time available, such as 10 per 100,000 person-years of cohort follow-up. The ratio of the observed cancer incidence to the expected incidence based on state rates (standardized incidence ratio, or SIR) would identify any differences in cancer rates between fire mechanics and California residents. While these types of studies are useful in identifying potential associations between

occupational groups and cancer, they are often confounded by underlying factors, such as different rates of smoking between the cohort and the general population.

An ideal comparison population to evaluate the risk of cancer in fire mechanics would comprise a demographically similar population. A group of workers with similar distributions of age, sex, race, smoking history, and socioeconomic status would control for potentially confounding variables and isolate the risk factor of working as a fire mechanic. One potential comparison group could be other mechanics in LA County outside of the Fire Department. These employees would likely have demographics similar to those of the fire mechanics, without exposure to firefighting equipment and vehicles. The comparison group could be identified with job classification codes in the eHR system and linked to the CCR. However, it is unclear how many persons would make up a cohort of general mechanics and whether the sample would be large enough to detect statistically significant risks.

#### 4.6 Additional Considerations

A theoretical calculation was conducted to estimate whether the potential cohort size (n=180) would be large enough to detect a significant risk of cancer compared to the general population. The CCR online analysis tool (CAL\*Explorer) was used to determine the incidence rate of all cancers among residents of LA County (386.3 per 100,000). The risk of cancer among fire mechanics was assumed to be the same as the highest risk of a specific cancer site observed among firefighters (50% increased risk of testicular cancer, [IARC 2010], as no summary of the risk of all cancers was available). A power calculation was conducted and determined that approximately 10,000 person-years of time would be required. Assuming an average of 10 years of follow-up (time from beginning occupation as a fire mechanic to latest date cancer data is available), approximately 1000 fire mechanics would be needed to detect a significantly increased risk of cancer.

#### 5 Conclusions and Recommendations

The epidemiologic feasibility study determined that a cohort of fire mechanics in LA County could be assembled, identifying employees holding relevant occupational positions since 1975 and linked to the California Cancer Registry and/or NDI for cancer outcomes. However, the size of the potential cohort would be relatively small (preliminary estimate of 180 employees from 1975–2021), limiting the ability to detect any risk of cancer in this population. Conducting an epidemiologic study in this potential cohort would not produce meaningful results. If the cancer risk in fire mechanics was similar to that of firefighters, at least 1000 fire mechanics would be needed to determine a significant increased risk of cancer.

#### 5.1 Recommendation

Evaluate potential of expanding the cohort to fire mechanics throughout the state of California.

The cohort of fire mechanics could be reliably constructed using job classification codes and personnel records in LA County and could be tracked for cancer outcomes using the CCR and/or NDI. To increase statistical power and precision, the feasibility of expanding the cohort to fire mechanics throughout California could be explored. If other counties use the same personnel records system and job classification codes, including all fire mechanics in the State of California in the cohort, it would be straightforward. Cancer incidence and mortality rates could be calculated for the cohort and compared to rates in LA County and the State of California after standardizing the rates by age, sex, and race. A larger cohort size would increase the statistical ability to detect any significant cancer risk in these workers. Further, if an increased risk of one or more cancer sites is detected within the cohort, nested case-control studies can be conducted to evaluate specific risk factors within the cohort for these cancer types (e.g., certain job tasks, exposures, or demographic factors).

#### 1 Background

ToxStrategies was contracted by the California Department of Industrial Relations (DIR), Commission on Health and Safety and Workers' Compensation (CHSWC), to conduct the study as outlined in California Assembly Bill (AB) 1400. AB 1400 was created to define the fire mechanics' risk of exposures to carcinogens in the course of employment.

The study components include:

- Site visits to representative facilities in Los Angeles County, California
- Interviews and surveys with current and former fire mechanics
- Feasibility study to assess cancer incidence among fire mechanics
- Occupational exposure measurements of carcinogens found in the workplace, to evaluate potential exposure to carcinogenic materials
- Quantitative health risk assessment of potential increased cancer risk associated with exposure to carcinogens in the workplace.

ToxStrategies' approach to address these study components includes six tasks (provided in our proposal submitted to the DIR [ToxStrategies, Inc., 2020a]):

- Task 1: Structured literature review submitted; ToxStrategies, Inc. (2020b)
- Task 2: Qualitative exposure assessment submitted; ToxStrategies, Inc. (2020c)
- Task 3: Epidemiologic assessment feasibility study of cohort enumeration for future epidemiologic study design ongoing
- Task 4: Quantitative exposure assessment measurement of current occupational exposures to carcinogens; provided herein
- Task 5: Cancer risk assessment calculation of theoretical excess cancer risks from occupational exposure to carcinogens
- Task 6: Technical assistance to the DIR.

The purpose of Task 4, Quantitative Exposure Assessment, was to conduct exposure monitoring of workers for airborne chemicals, as well as chemical analysis of surface residues, based on the findings from Tasks 1 and 2. Samples from each similar exposure group (SEG) were selected for personal breathing-zone (PBZ) air sampling and surface wipe sampling of equipment. The quantitative exposure results from Task 4 will be used subsequently in the cancer risk assessment (Task 5). The objectives, methods, results, and conclusions of Task 4 are provided herein. The remaining study tasks are described in Section 7.

#### 2 Objectives

The objectives of this quantitative exposure assessment were as follows:

- 1. Prepare a quantitative exposure assessment work plan.
- 2. Collect PBZ air samples and surface wipe samples for analysis at an American Industrial Hygiene Association (AIHA)-accredited laboratory.
- 3. Present the analytical sample results (measurements) for each of the prioritized job tasks.

### 3 Methods of Selecting Carcinogens

The identification and selection of chemicals for analytical sampling, for each of the prioritized job tasks, included the evaluation of findings from Task 1, Task 2, and other sources, as summarized below.

#### 3.1 Task 1 Findings

ToxStrategies identified chemicals in Task 1 (Structured Literature Review; ToxStrategies, Inc., 2020b) for consideration in the quantitative exposure assessment, and additional chemicals were added to the analysis plan following Task 2 (Qualitative Exposure Assessment). In Task 1, ToxStrategies found no occupational chemical exposure studies that explicitly focused on fire mechanics. However, nine industrial hygiene studies presented data for fire stations and firefighting vehicles and/or gear, which could overlap with occupational exposures of fire mechanics. The chemical carcinogens evaluated in those studies, or considered subsequently for inclusion, are benzene, diesel exhaust, polycyclic aromatic hydrocarbons (PAHs), crystalline silica, ethylbenzene, polychlorinated biphenyls (PCBs), organochlorine pesticides (OCPs), acetaldehyde, formaldehyde, 1,4-dichlorobenzene, and styrene. Benzene, diesel exhaust, PAHs, crystalline silica, and ethylbenzene were identified in Task 2 for inclusion in the quantitative assessment. OCPs and 1,4-dichlorobenzene were not included in the analyses for Task 4, for the following reasons:

- OCPs were excluded from incorporation into the sampling plan, based on the results of the study by Park et al. (2015) and the findings presented in IARC (2010). Park et al. found that firefighting was not a significant source of exposure to OCPs. Further, IARC did not report OCPs in their list of chemicals measured during various firefighting operations (wildland, municipal, training, or arson investigation).
- 1,4-Dichlorobenzene was excluded from consideration in the sampling plan, because Fent et al. (2015) reported that firefighters' brand new personal protective equipment (PPE) had a higher measured off-gassing air concentration of 1,4-dichlorobenzene than that of the used PPE that had been exposed to a controlled burn. Therefore, off-gassing of 1,4-dichlorobenzene was not associ-

ated with the burn, but presumably, was associated with the chemicals used in manufacturing the PPE.

PCBs, styrene, acetaldehyde, and formaldehyde were included in the Task 4 investigation, for the following reasons:

- PCBs were not found to be a significant source of exposure among firefighters, when measured in firefighter serum in the study by Park et al. (2015). However, IARC (2010) reported PCBs in their list of chemicals measured during municipal firefighting operations. Therefore, PCBs were included in the sampling plan for surface wipe analysis.
- Styrene was reported to have higher measured off-gassing in used firefighters' PPE that had been exposed to a controlled burn than the measured background levels (Fent et al., 2015). Therefore, styrene was added to the air sampling plan for the SEG of equipment maintenance workers.
- Acetaldehyde and formaldehyde were measured at low levels during wildland firefighting by Materna et al. (1992); therefore, these aldehydes were both included in the PBZ air sampling plan for the SEG of equipment maintenance workers.

#### 3.2 Task 2 Findings

ToxStrategies relied primarily on the findings from Task 2, Qualitative Exposure Assessment (ToxStrategies, Inc., 2020c), to prioritize the chemicals included in the PBZ air samples and surface wipe samples. A qualitative exposure assessment tool was used to rank potential exposures associated with jobs and tasks to carcinogens identified in the workplace. This tool allowed ToxStrategies to target the DIR resources for Task 4 most cost-effectively. Based on the outcome of the risk ranking results for all four SEGs, ToxStrategies prioritized the job tasks listed in Table 1 for the quantitative exposure assessment.

ToxStrategies identified the surface residue, soot, as a priority carcinogen to measure during the quantitative exposure assessment. Soot, ash, and char are considered fire residues and have the potential to pose an occupational exposure concern for fire mechanics who frequently contact fire apparatuses and equipment that have been exposed to a fire. The chemicals that make up this residue may include "heavy metals, PAHs, dioxins and furans" (AIHA, 2018). PAHs, dioxins, and furans were thus added to the sampling plan for surface sampling of fire residues. With regard to the heavy metals, ToxStrategies included arsenic and lead, because both have published cancer potency measures for the oral route, which can be evaluated for cancer risk through a surface wipe sample. ToxStrategies excluded cadmium, beryllium, nickel, and cobalt from the surface wipe sampling plan, because these chemicals are carcinogenic only by inhalation and do not have published cancer potency measures for other routes of exposure. Therefore, they were not evaluated in surface wipe samples.

Table 1. Job tasks prioritized for the quantitative exposure assessment

| Job Task                                                             | Similar Exposure Group                | Location                                                            |
|----------------------------------------------------------------------|---------------------------------------|---------------------------------------------------------------------|
| Heavy maintenance on aircraft, including the task of oil leak checks | Helicopter mechanic                   | Air Operations, Pacoima                                             |
| Intermediate maintenance on aircraft                                 | Helicopter mechanic                   | Air Operations, Pacoima                                             |
| Painting/priming/sanding aircraft parts                              | Helicopter maintenance inspector      | Air Operations, Pacoima                                             |
| Repair and tune-up of power equipment and rescue tools               | Equipment maintenance worker          | Breathing Apparatus Shop, Pacoima                                   |
| Fire hose repair                                                     | Equipment maintenance worker          | Breathing Apparatus Shop, Pacoima                                   |
| Maintenance and repair on fire apparatus                             | Shop-assigned fire equipment mechanic | Eastern Fire Shop, Los Angeles, & North County Fire Shop, Lancaster |
| Repair of fire apparatus or other equipment at a wildfire base camp  | Field-assigned FEM                    | Wildfire base camp                                                  |

#### 3.3 Other Findings

A recent study by Fent et al. (2020) reported detections of the carcinogenic flame retardant, tetrabromobisphenol-A, and chlorinated and brominated dioxins/furans in wipe samples of firefighters' PPE subsequent to exposure to a simulated residential fire. Tetrabromobisphenol-A and chlorinated and brominated dioxins/furans were also detected in air samples collected during the active fire period of the simulated residential fire. Because tetrabromobisphenol-A does not have published cancer potency measures, it cannot be evaluated quantitatively, and therefore, it was not included in the sampling plan for wipe analysis. However, chlorinated dioxins and furans were added to the sampling plan for wipe analysis for all five SEGs based on the findings of this study.

ToxStrategies added the carcinogen pentachlorophenol to the sampling plan based on the data reported in IARC (2010). Pentachlorophenol was detected in air samples measured in municipal fires; thus, this chemical was suspected to be a fire residue in fire equipment and apparatuses. Therefore, pentachlorophenol was added to the sampling plan for wipe analysis for the SEGs of fire equipment mechanic and equipment maintenance workers.

### 4 Sampling Plan

The final sampling plan is summarized below for each SEG and job task (Table 2). Execution of the sampling plan for each job task is described in more detail below.

Table 2. Quantitative assessment plan by SEG and job task

|                                                                               | Job Task Description                                                 | Job Title                                                   | Exposure Media                                                                                                                                                         | a and Chemicals                                                                                                                        |

#### 4.1 Air Operations, Pacoima

#### 4.1.1 Heavy maintenance on aircraft, including the task of oil-leak checks

Heavy maintenance on the aircraft by helicopter mechanics typically takes place inside the hangar, and includes disassembling and reassembling airframes, engines, and other components and parts. The mechanics generally wear a uniform, work boots, goggles/safety glasses, hearing protection, gloves (type dependent on task), and knee pads.

Personal breathing zone air samples were collected from six helicopter mechanics and analyzed for the following chemicals:

- Crystalline silica by NIOSH 7500 (modified [Mod.]) and 0600 using a 5-μm (micrometer) polyvinyl chloride (PVC) membrane and tared 5-μm PVC membrane in a three-piece cassette with aluminum cyclone
- Hexavalent chromium by OSHA ID-215 (version 2) using a 5-μm PVC membrane in a 37-mm (millimeter) cassette.

Wipe samples of the helicopter surfaces were collected in accordance with NIOSH Method 9100 (NIOSH, 1996) using a 10- x 10-centimeter (cm) square template. One template and a new pair of gloves were used for each wipe sample. Six surfaces were sampled for the following chemicals:

- PAHs by NIOSH 5528 using hexane-extracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes.

Two surfaces were sampled for hexavalent chromium by OSHA ID-215 using a 37-mm sodium hydroxide—coated binderless quartz (NaOHqz) fiber filter wipe.

The chemicals, sample identifiers (IDs), sampling locations, and observations/notes are summarized in Table 3 for the wipe samples collected on various surfaces of the aircrafts stationed in the hangar for heavy maintenance on November 3, 2020.

Table 3. Wipe samples collected on aircrafts in hangar

One field blank per analyte was collected for quality assurance.

#### 4.1.2 Intermediate maintenance on aircraft

Intermediate maintenance includes routine daily inspection and maintenance on the aircraft by helicopter mechanics. This task is approximately an hour in duration and typically takes place outdoors on the flight line or in a covered area off the flight line. PPE includes work boots, work uniform, goggles/safety glasses, hearing protection, gloves (depending on task), and knee pads. Intermediate maintenance is performed at the start of the work shift. After the intermediate maintenance is completed each day, the helicopter mechanics return to the hangar and conduct heavy maintenance on the aircraft. The intermediate maintenance helicopter mechanics were measured during their entire work shift; therefore, the occupa-

tional exposure samples capture both intermediate maintenance and heavy maintenance on the aircraft, with the latter task constituting the bulk of the measurements.

PBZ air sampling was measured among six helicopter mechanics for the following chemicals:

- Benzene, ethylbenzene, and naphthalene using a 3M 3500/3520 organic vapor monitor
- Hexavalent chromium by OSHA ID-215 (version 2) using a 5-μm PVC membrane in a 37-mm cassette.

Wipe samples of the helicopter surfaces were collected in accordance with NIOSH Method 9100 (NIOSH, 1996) using a 10- x 10-cm square template. One template and a new pair of gloves were used for each wipe sample.

Six surfaces were sampled for the following chemicals:

- Polycyclic aromatic hydrocarbons (PAHs) by NIOSH 5528 using hexaneextracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes
- Hexavalent chromium by OSHA ID-215 using a 37-mm NaOHqz fiber filter.

Two surfaces were sampled for the following chemicals:

• Chlorinated dioxins/furans by EPA 1613B and PCBs by EPA 1668C using swabs soaked in hexane.

The chemicals, sample IDs, sampling locations, and observations/notes are summarized in Table 4 for the wipe samples collected on various surfaces of the aircrafts parked on the flight line for intermediate maintenance on November 3, 2020.

 Table 4.
 Wipe samples collected on aircraft on the flight line

| Chemical               | Sample ID       | Sampling Location                           | Observations/ Notes                                   |
|------------------------|-----------------|---------------------------------------------|-------------------------------------------------------|
| PAHs                   | N822LA-01       | Right engine exhaust cowling of Firehawk    | Firehawk had been to a recent wildfire (October 2020) |

| Hexavalent<br>Chromium             | N120LA-02 | Hot part of left engine (seam) of Bell412 |                     |
| Hexavalent<br>Chromium             | N17LA-03  | Hot part of left engine (seam) of Bell412 |                     |
| Chlorinated dioxins/ furans & PCBs | 356-4     | Horizontal stabilator of<br>Bell412       |                     |
| Chlorinated dioxins/ furans & PCBs | 356-5     | Chin bubble of Bell412                    |                     |

Field blanks were collected for quality assurance, as applicable.

Although diethanolamine and tetrahydrofuran were also considered potential carcinogens of concern for this job task, these compounds were not measured quantitatively, because they do not have published cancer potency measures. Thus, the cancer risk assessments conducted in Task 5 for these chemicals will be qualitative.

#### 4.1.3 Painting/priming/sanding aircraft parts

For the helicopter maintenance inspector job task of painting/priming on the interior and exterior of the aircraft, sanding helicopter blades, painting helicopter blades, and painting using aerosol paints and epoxy primers, ToxStrategies planned to measure one helicopter maintenance inspector for the following chemicals through PBZ air sampling:

- Ethylbenzene using a 3M 3500/3520 organic vapor monitor
- Hexavalent chromium by OSHA ID-215 (version 2) using a 5-μm PVC membrane in a 37-mm cassette
- Methylene chloride using a 3M 3520 two-stage organic vapor monitor
- 4-Chlorobenzotrifluoride by NIOSH 1026 using a coconut shell charcoal sorbent tube.

However, ToxStrategies was informed by Air Operations shortly before the scheduled sampling event that this job task would not be performed and therefore could not be measured, because no paint jobs were needed at the time. Therefore, the cancer risk assessment (Task 5) for these chemicals in this job task will be qualitative.

#### 4.1.4 Area samples

ToxStrategies collected two area PBZ air samples to be analyzed for the following chemicals:

 Benzene, ethylbenzene, and naphthalene using a 3M 3500/3520 organic vapor monitor.

Because a field blank had already been collected for each of these chemicals, no additional field blanks were collected.

#### 4.2 Breathing Apparatus Shop, Pacoima

#### 4.2.1 Repair and tune-up of power equipment and rescue tools

Shop locations at Pacoima include the Breathing Apparatus (BA) Shop, Small Engine Repair Shop, and Fire Hose Repair Shop. At the Small Engine Repair Shop, worker tasks include equipment examination and analysis of equipment malfunctions or mechanical failure. Other tasks include tuning up equipment used by the County fire stations, such as rescue tools, lawn mowers, vacuums, and generators. At the Fire Hose Repair Shop, the workers are responsible for repairing fire-truck hoses and completing the hose test. Equipment, such as firefighter BAs, is maintained and tested at the Pacoima BA Shop. BAs used during fire training in simulated structure burns, such as that conducted at the Los Angeles County Fire Department Fire Station 129 in Lancaster, are maintained at the BA Pacoima shop. The workers' PPE includes latex gloves and an apron.

At the Engine Repair Shop, PBZ air samples were collected among two equipment maintenance workers for the following chemicals:

- Benzene, ethylbenzene, naphthalene, and styrene using a 3M 3500/3520 organic vapor monitor
- Acetaldehyde and formaldehyde by EPA TO-11A using an SKC 500-100, UMEx 100 passive sampler.

Wipe samples of the air packs (exterior surfaces) were collected in accordance with NIOSH Method 9100 (NIOSH, 1996) using a 10- x 10-cm square template. One template and a new pair of gloves were used for each wipe sample. Six air packs were sampled for the following chemicals:

- PAHs by NIOSH 5528 using hexane-extracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes.

Two air packs (exterior surfaces) were sampled for the following chemicals:

• Chlorinated dioxins/furans by EPA 1613B and PCBs by EPA 1668C using swabs soaked in hexane.

• Pentachlorophenol by OSHA 39 using sterile cotton gauze soaked in deionized (DI) water.

The chemicals, sample IDs, sampling locations, and observations/notes are summarized in Table 5 for the wipe samples collected on the field and training air packs in the BA shop on November 3, 2020.

Table 5. Wipe samples collected on air packs

| Chemical                           | Sample ID          | Sampling Location                      | Observations/ Notes                |
|------------------------------------|--------------------|----------------------------------------|------------------------------------|
| PAHs                               | A49996             | Where air pump sits, northern location | Field air pack                     |
| PAHs                               | A50421 ENG-21-4    | Where air pump sits, northern location | Field air pack                     |
| PAHs                               | A5014 Q-24-5       | Where air pump sits, northern location | Field air pack                     |
| PAHs                               | ECTC-T-8           | Where air pump sits, northern location | Training air pack                  |
| PAHs                               | ECTC-T-38          | Where air pump sits, northern location | Training air pack                  |
| PAHs                               | NCSO-04            | Where air pump sits, northern location | Training air pack                  |
| Arsenic and lead                   | ECTC-T-8-A         | Where pump sits, southern location     | Training air pack                  |
| Arsenic and lead                   | ECTC-T-38-A        | Where pump sits, southern location     | Training air pack                  |
| Arsenic and lead                   | A49996-QUT-185-4-A | Where pump sits, southern location     | Field air pack                     |
| Arsenic and lead                   | A50143-Q-24-5-A    | Where pump sits, southern location     | Field air pack                     |
| Arsenic and lead                   | NC50-4-A           | Where pump sits, southern location     | Training air pack                  |
| Arsenic and lead                   | AS0421-ENG-21-4-A  | Where pump sits, southern location     | Field air pack                     |
| Chlorinated dioxins/ furans & PCBs | BA-1               | Where pump sits, middle portion        | Field air pack;<br>AS0421-Eng-21-4 |

| Chemical                           | Sample ID     | Sampling Location               | Observations/ Notes             |
|------------------------------------|---------------|---------------------------------|---------------------------------|
| Chlorinated dioxins/ furans & PCBs | BA-2          | Where pump sits, middle portion | Training air pack;<br>ECTC-T-42 |
| Pentachlorophenol                  | A50143-Q-24-5 | Where pump sits, middle portion | Field air pack                  |
| Pentachlorophenol                  | ECTC-T-7      | Where pump sits, middle portion | Training air pack               |

Field blanks were collected for quality assurance, as applicable.

#### 4.2.2 Fire hose repair

Wipe samples of used fire hoses (exterior surfaces) were collected in accordance with NIOSH Method 9100 (NIOSH, 1996) using a 10- x 10-cm square template. One template and a new pair of gloves were used for each wipe sample. Six fire hoses were sampled for the following chemicals:

- PAHs by NIOSH 5528 using hexane-extracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes.

The chemicals, sample IDs, sampling locations, and observations/notes are summarized in Table 6 for the wipe samples collected on the fire hoses on November 3, 2020.

Table 6. Wipe samples collected on fire hoses

| Chemical         | Sample ID | Sampling Location | Observations/ Notes   |
|------------------|-----------|-------------------|-----------------------|
| PAHs             | H-01      | Exterior of hose  | Fire hose, very dirty |
| PAHs             | H-02      | Exterior of hose  | Fire hose             |
| PAHs             | H-03      | Exterior of hose  | Fire hose             |
| PAHs             | H-04      | Exterior of hose  | Fire hose, very dirty |
| PAHs             | H-05      | Exterior of hose  | Fire hose, very dirty |
| PAHs             | H-06      | Exterior of hose  | Fire hose             |
| Arsenic and lead | H-01-A    | Exterior of hose  | Fire hose             |
| Arsenic and lead | H-02-A    | Exterior of hose  | Fire hose             |
| Arsenic and lead | H-03-A    | Exterior of hose  | Fire hose             |

| Chemical         | Sample ID | Sampling Location | Observations/ Notes |
|------------------|-----------|-------------------|---------------------|
| Arsenic and lead | H-04-A    | Exterior of hose  | Fire hose           |
| Arsenic and lead | H-05-A    | Exterior of hose  | Fire hose           |
| Arsenic and lead | H-06-A    | Exterior of hose  | Fire hose           |

Field blanks were collected for quality assurance, as applicable.

#### 4.3 Eastern Fire Shop, Los Angeles

#### 4.3.1 Maintenance and repair on fire apparatus

Shop-assigned Fire Equipment Mechanics (FEMs) typically work on the major repairs such as engine and transmission changes, in-frame engine rebuilds, differential exchanges and rebuilds, major pump repair, plumbing issues, and water tank removal, and they are required to do more welding for significant parts repair and replacement. PPE among the FEMs varies depending on task. For example, during welding, PPE includes a welding helmet, welding gloves, and an N95 respirator; when painting, PPE includes latex gloves, eye protection, and an N95 respirator. Goggles (or other eye protection), latex gloves, and knee pads are used for other FEM tasks.

PBZ air samples were collected among six FEMs for the following chemicals:

- Benzene, ethylbenzene, and naphthalene using a 3M 3500/3520 organic vapor monitor
- Diesel particulate (as elemental carbon) by NIOSH 5040 using a quartz-fiber filter in a three-piece 37-mm cassette
- Welding fume metals by NIOSH 7300 Mod. using 0.8-μm mixed cellulose ester membrane in a two-piece 37-mm cassette
- Hexavalent chromium (in welding fume) by OSHA ID-215 (version 2) using a 5-μm PVC membrane in a 37-mm cassette
- N,N-Dimethyl-para-toluidine by NIOSH 2002 (Issue 2) using an SKC 226-98, XAD-7 (phosphoric acid) sorbent tube
- Tetrachloroethylene by NIOSH 1003 using an SKC 226-01, charcoal tube (100/50 mg).

Wipe samples on the fire trucks were collected in accordance with NIOSH Method 9100 (NIOSH, 1996) using a 10- x 10-cm square template. One template and a new pair of gloves were used for each wipe sample. Six locations on the fire truck were sampled for the following chemicals:

- PAHs by NIOSH 5528 using hexane-extracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes
- Pentachlorophenol by OSHA 39 using sterile cotton gauze soaked in DI water
- Chlorinated dioxins/furans by EPA 1613B and PCBs by EPA 1668C using swabs soaked in hexane.

The chemicals, sample IDs, sampling locations, and observations/notes are summarized in Table 7 for the wipe samples collected on various surfaces of the fire trucks at the Eastern Fire Shop on November 4, 2020.

Table 7. Wipe sample collected on fire trucks

| Chemical                           | Sample ID      | Sampling Location                                               | Observations/ Notes                                                  |
|------------------------------------|----------------|-----------------------------------------------------------------|----------------------------------------------------------------------|

In addition, four bulk samples of the vermiculite-coated fiberglass strips were analyzed for asbestos.

One field blank was collected from each of the analyses listed above, except for the bulk samples.

#### 4.3.2 Area samples

ToxStrategies collected two area PBZ air samples to be analyzed for the following chemicals:

- Benzene, ethylbenzene, and naphthalene using a 3M 3500/3520 organic vapor monitor
- Diesel particulate (as elemental carbon) by NIOSH 5040 using a quartz-fiber filter in a three-piece 37-mm cassette.

Because a field blank was collected for each of these chemicals, as described in Section 4.3.1, no additional field blanks were collected.

Cumene, tetrabromobisphenol-A, and methyl isobutyl ketone were also considered potential carcinogens of concern for the job task at the Eastern Fire Shop; however, these compounds were not measured quantitatively, because they do not have published cancer potency measures. Thus, their cancer risk assessment (Task 5) will be qualitative only.

#### 4.4 Wildfire Base Camp, Los Angeles County

#### 4.4.1 Repair of fire apparatus or other equipment

For the field-assigned FEM, the job task of repairing fire apparatuses or other equipment at a wildfire base camp ranked very high and was thus considered a high priority for Task 4. ToxStrategies planned to conduct PBZ air sampling among three field FEMs for the following chemicals:

- Acetaldehyde and formaldehyde by EPA TO-11A using an SKC 500-100, UMEx 100 passive sampler
- Benzene, ethylbenzene, and naphthalene using a 3M 3500/3520 organic vapor monitor
- Diesel particulates (as elemental carbon) by NIOSH 5040 using a quartz-fiber filter in a three-piece 37-mm cassette
- PAHs by NIOSH 5528 (draft) using a SKC 226-57, OSHA versatile sampler (XAD-7, glass fiber filter) tube.

Wipe samples on fire trucks and other field equipment that a field FEM would contact were planned to be collected for the following chemicals:

- PAHs by NIOSH 5528 using hexane-extracted gauze
- Arsenic and lead by NIOSH 9102 Mod. using Ghost Wipes
- Pentachlorophenol by OSHA 39 using sterile cotton gauze soaked in DI water
- Chlorinated dioxins/furans by EPA 1613B and PCBs by EPA 1668C using swabs soaked in hexane.

However, at the time of the study, there were no active fires in Los Angeles County; therefore, this job task will be assessed using the scientific literature for the cancer risk assessment in Task 5.

#### 4.5 Calibration of PBZ Air Samples

Personal air sampling pumps were calibrated using a primary or secondary calibration device, with the tubing and sampling cassette connected in-line. Pre- and post-flow rates were measured directly before and after the PBZ air sample was collected; flow rates that had a difference of greater than 5% were identified as estimated. Each analytical method defines the recommended flow rates.

#### 4.6 Laboratory Analysis

Most samples were analyzed by ALS Environmental, an AIHA-accredited laboratory, in Salt Lake City, Utah, under a standard turnaround time. The exception was the dioxins, furans, and PCB samples, which were shipped to ALS Environmental in Burlington, Ontario.

#### 5 Results

The analytical results for the submitted samples are presented below for each SEG and job task, and the laboratory reports are included in Attachment 1.

#### 5.1 Air Operations, Pacoima (November 3, 2020)

#### 5.1.1 PBZ air samples

Hexavalent chromium was measured in one sample collected among helicopter mechanics performing intermediate and heavy maintenance on the aircraft. One sample from each of these job tasks had a personal sampling air pump that failed during the sampling event; therefore, these samples were discarded and not analyzed. The analytical results are provided in Table 8.

Respirable crystalline silica as quartz, cristobalite, and tridymite were sampled among helicopter mechanics performing heavy maintenance on the aircraft. The analytical results are provided in Table 9. Respirable crystalline silica as quartz, cristobalite, and tridymite were not measured in any sample (Table 9).

Benzene, ethylbenzene, and naphthalene were analyzed in samples collected among helicopter mechanics performing intermediate maintenance on the aircraft. Two area samples were also measured in the hanger. One area sample was collected along the southwest wall, and one sample was collected in the work area. The analytical results are provided in Table 10; benzene, ethylbenzene, and naphthalene were not detected in any sample (Table 10).

Table 8. Hexavalent chromium personal breathing zone (PBZ) air sampling results analyzed by OSHA ID-215

<sup>† 8</sup> CCR§1532.3 for respirable crystalline silica (quartz, cristobalite, and/or tridymite)

Abbreviations: <= not detected; Cal/OSHA = California Division of Occupational Safety and Health (DOSH); CCR = California Code of Regulations; hr = hour; mg/m³ = milligrams per cubic meter of air; TWA = time-weighted average

<sup>\*</sup> Sample duration is uncertain; personal sampling air pump faulted between the times of 1:30pm and 3:15pm. Sample duration is based on an estimated sample end time of 2:30pm. The results may be biased high, but they were all non-detect.

<sup>†8</sup> CCR§5218 for benzene (converted ppm units to mg/m³ using molar volume in liters at normal temperature and pressure [0 °C, 760 mmHg]), Title 8, Table AC-1 for ethylbenzene and naphthalene

Abbreviations: <= not detected; Cal/OSHA = California Division of Occupational Safety and Health (DOSH); CCR = California Code of Regulations; hr = hour; TWA = time-weighted average; mg/m<sup>3</sup> = milligrams per cubic meter of air; PEL = permissible exposure limit; ppm = parts per million by volume; NA = not available

#### 5.1.2 Surface wipe samples (November 3, 2020)

A Firehawk and a Bell412 were parked inside the hangar for heavy maintenance. PAHs, arsenic, lead, and hexavalent chromium were analyzed for in wipe samples from various locations of these aircraft. The analytical results are provided in Table 11. Only hexavalent chromium and lead were measurable in any sample; no other chemicals were detected (Table 11).

Table 11. Wipe sample results on aircrafts in hangar

Abbreviations: <= not detected;  $\mu g/cm^2 =$  micrograms per square centimeter; \* = not considered a carcinogen **Bold** indicates detected result.

A combination of Firehawks and Bell412s were parked outside on the flight line. PAHs, arsenic, lead, hexavalent chromium, chlorinated dioxins/furans, and PCBs were analyzed for in wipe samples from various locations of the aircraft. The analytical results are provided in Table 12. The analytical results for chlorinated dioxins/furans and PCBs were converted to a 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) toxic equivalence (TEO) concentration. Note that there are only 12 PCB congeners with published congener-specific toxicity equivalency factors (TEFs) (DTSC HERO, 2017; USEPA, 2010; van den Berg et al., 2006 [WHO report]). The TEQ is calculated by multiplying the TEF, which is an estimate of the congener-specific toxicity/potency relative to the toxicity/potency of TCDD (TEF value of 1), by the detected concentration of the dioxin or dioxin-like congener (DTSC HERO, 2017; USEPA, 2010; van den Berg et al., 2006 [WHO report]). The individual TEQ concentrations are then summed to yield the total TEO concentration for that sample. Therefore, the calculated TEQs are presented for chlorinated dioxins/furans and PCBs, where applicable. The non-TEQ PCBs total is also presented for each sample, which is calculated by summing the individual congeners without a TEF. Congeners that were non-detects were assigned values equal to 50% of the reporting limit for calculating the dioxin/furan/PCB TEQ and non-TEQ PCB totals for each sample. The laboratory reports found in Attachment 1 present the analytical results for each congener. Attachment 2 contains the analytical results by PCB and dioxin/furan congener (µg/cm<sup>2</sup>), TEFs applied, and TEQ calculations by Sample ID. PAHs and arsenic were not measured in any sample.

Table 12. Wipe sample results on aircrafts on flight line

Abbreviations: <= not detected;  $\mu g/cm^2 =$  micrograms per square centimeter; TEQ = 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) toxic equivalence; TEQ concentrations are calculated by multiplying the toxic equivalency factor (TEF) by the detected concentration of the dioxin or dioxin-like congener (dioxin/furan/PCB); \*= not considered a carcinogen

**Bold** indicates detected result.

<sup>†</sup> Congeners that were non-detects were assigned values equal to 50% of the detection limit.

# 5.2 Breathing Apparatus Shop, Pacoima (November 3, 2020)

# 5.2.1 PBZ air samples

Benzene, ethylbenzene, naphthalene, styrene, acetaldehyde, and formaldehyde were analyzed in PBZ air samples collected among equipment maintenance workers in the small-engine repair shop. The analytical results are provided in Table 13 for benzene, ethylbenzene, naphthalene, and styrene, and in Table 14 results for acetaldehyde and formaldehyde are presented. Benzene, acetaldehyde, and formaldehyde were detected.

# 5.2.2 Surface wipe samples

PAHs, arsenic, lead, chlorinated dioxins/furans, PCBs, and pentachlorophenol were analyzed in wipe samples collected from training and field air packs. PAHs, lead, chlorinated dioxins/furans, and PCBs were detected. The analytical results are provided in Table 15. Chlorinated dioxin/furan and PCB TEQ and non-TEQ totals, where applicable, are presented below; the analytical results for each congener are presented in the laboratory reports (Attachment 1). Congeners that were non-detects were assigned values equal to 50% of the reporting limit for calculating the dioxin/furan/PCB TEQ and non-TEQ PCB totals for each sample. Attachment 2 contains the analytical results by PCB and dioxin/furan congener (μg/cm²), TEFs applied, and TEQ calculations by Sample ID.

Table 15. Wipe sample results on air packs

Abbreviations: <= not detected;  $\mu g/cm^2 =$  micrograms per square centimeter; TEQ = 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) toxic equivalence; TEQ concentrations are calculated by multiplying the toxic equivalency factor (TEF) by the detected concentration of the dioxin or dioxin-like congener (dioxin/furan/PCB); \* = not considered a carcinogen

**Bold** indicates detected result.

PAHs, arsenic, and lead were analyzed in wipe samples on exterior locations of the fire hose. Lead was detected in each of the six surface wipes collected; PAHs and arsenic were not detected in any of the samples. The analytical results are provided in Table 16 below.

<sup>†</sup> Congeners that were non-detects were assigned values equal to 50% of the detection limit.

Table 16. Wipe sample results on fire hoses

**Bold** indicates detected result.

# 5.3 Eastern Fire Shop, Los Angeles (November 4, 2020)

# 5.3.1 PBZ air samples

Benzene, ethylbenzene, naphthalene, and diesel particulate as elemental carbon were analyzed in PBZ air samples among fire equipment mechanics performing maintenance on the fire apparatus. Two area samples were also analyzed for each of these chemicals in the Eastern Fire Shop. One area sample was collected in the center third aisle column (from the south entrance), and one sample was collected in the third bay along the west side (on

the workbench) of the Eastern Fire Shop. The analytical results are provided in Table 17 for benzene, ethylbenzene, and naphthalene, and in Table 18 for diesel particulate matter as elemental carbon. Benzene, ethylbenzene, and naphthalene were not measured in any sample; diesel particulate matter as elemental carbon was detected in one sample.

Table 17. Benzene, ethylbenzene, and naphthalene personal breathing zone (PBZ) air sampling results analyzed by 3M 3500/3520 POVM

PBZ air samples for two fire equipment mechanics were analyzed for welding-fume metals, including hexavalent chromium. During the welding activity, the fire equipment mechanics were a half-face P-100 respirator with a face shield. The total welding time was approximately 30 to 45 minutes, and the grinding/cutting time was approximately 4 hours. Both fire equipment mechanics performed MIG (metal inert gas) welding. Only cobalt and nickel were detected. The welding-fume metals and hexavalent chromium exposure results are presented in Tables 19 and 20, respectively.

Abbreviations: < = not detected; Cal/OSHA = California Division of Occupational Safety and Health (DOSH); CCR = California Code of Regulations; hr = hour; PEL = permissible exposure limit; TWA = time-weighted average; mg/m³ = milligrams per cubic meter of air

N,N-dimethyl-para-toluidine was analyzed in the PBZ air among six fire equipment mechanics performing maintenance on the fire apparatus; however, one personal sampling air pump failed during the sampling event; therefore, this sample was discarded and not analyzed. Sample ID 01875 had a measured pre- and post-flow rate that was different by approximately 13%; therefore, the reporting limit in the table is an estimate. The true reporting limit is between 0.00047 and 0.00055 mg/m³, assuming the pre-flow rate (minimum reporting limit value of <0.00047 mg/m³) and the post-flow rate (maximum reporting limit value of <0.00055 mg/m³) as the average flow rates used to calculate exposure. The analytical results for the remaining five samples are provided in Table 21 below; no samples were detected above the reporting limit.

<sup>†</sup> No Cal/OSHA PEL established

Abbreviations: <= not detected; Cal/OSHA = California Division of Occupational Safety and Health (DOSH); CCR = California Code of Regulations; hr = hour; mg/m<sup>3</sup> = millograms per cubic meter of air; PEL = permissible exposure limit; TWA = time-weighted average

<sup>\*</sup> The pre- and post- flow rate was different by approximately 13%; therefore, this reporting limit is an estimate (the true reporting limit is between 0.00047 and 0.00055 mg/m³).

Tetrachloroethylene was analyzed and detected in the PBZ air among six fire equipment mechanics performing maintenance on the fire apparatus on November 4, 2020. Three samples had a pre- and post-flow rate difference of greater than 5%. The samples and their estimated values are described below:

- Sample ID 72775 had a measured pre- and post-flow rate that was different by approximately 11%; therefore, the result in the table is an estimate. The true result is between 15 and 17 mg/m³, assuming the pre-flow rate (minimum value of 15 mg/m³) and the post-flow rate (maximum value of 17 mg/m³) as the average flow rates used to calculate exposure.
- Sample ID 72780 had a measured pre- and post-flow rate that was different by approximately 8%; therefore, the result in the table is an estimate. The true result is between 17 and 18 mg/m³, assuming the pre-flow rate (minimum value of 17 mg/m³) and the post-flow rate (maximum value of 18 mg/m³) as the average flow rates used to calculate exposure.
- Sample ID 72779 had a measured pre- and post-flow rate that was different by approximately 28%; therefore, the result in the table is an estimate. The true result is between 64 and 90 mg/m³, assuming the pre-flow rate (minimum value of 64 mg/m³) and the post-flow rate (maximum value of 90 mg/m³) as the average flow rates used to calculate exposure.

The exposure results for all six samples are provided in Table 22.

<sup>†</sup> Title 8, Table AC-1

#### **Bold** indicates detected result.

Abbreviations: Cal/OSHA = California Division of Occupational Safety and Health (DOSH); CCR = California Code of Regulations; hr = hour; PEL = permissible exposure limit; TWA = time-weighted average;  $mg/m^3 = millograms$  per cubic meter of air

<sup>\*</sup> The pre- and post- flow rate was different by approximately 11%; therefore, this result is an estimate (the true result is between 15 and 17 mg/m³).

<sup>\*\*</sup> The pre- and post- flow rate was different by approximately 8%; therefore, this result is an estimate (the true result is between 17 and 18 mg/m³).

<sup>\*\*\*</sup> The pre- and post- flow rate was different by approximately 28%; therefore, this result is an estimate (the true result is between 64 and 90 mg/m³).

# 5.3.2 Surface wipe samples

PAHs, pentachlorophenol, lead, arsenic, chlorinated dioxins/furans and PCBs were analyzed in wipe samples from various locations on the fire truck. Only lead, chlorinated dioxins/furans, and PCBs were detected. The analytical results are provided in Table 23. Chlorinated dioxin/furan and PCB TEQ and non-TEQ totals, where applicable, are presented below; the analytical results for each congener are presented in the laboratory reports (Attachment 1). Congeners that were non-detects were assigned values equal to 50% of the reporting limit for calculating the dioxin/furan/PCB TEQ and non-TEQ PCB totals for each sample. Attachment 2 contains the analytical results by PCB and dioxin/furan congener (μg/cm²), TEFs applied, and TEQ calculations by Sample ID.

Table 23. Wipe sample results on fire trucks

Abbreviations: <= not detected;  $\mu$ g/cm² = micrograms per square centimeter; TEQ = 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) toxic equivalence; TEQ concentrations are calculated by multiplying the toxic equivalency factor (TEF) by the detected concentration of the dioxin or dioxin-like congener (dioxin/furan/PCB); \* = not considered a carcinogen

**Bold** indicates detected result.

<sup>†</sup> Congeners that were non-detects were assigned values equal to 50% of the detection limit.

# 5.3.3 Asbestos bulk samples

Four bulk samples of the vermiculite-coated fiberglass strips used to wrap the exhaust of a fire apparatus were analyzed for asbestos (chrysotile, amosite, crocidolite, actinolite/tremolite, and anthophyllite). Historically, vermiculite had the potential to contain traces of asbestos, which is a carcinogen. Based on the results from the four samples, presented in Table 24, no asbestos was detected. The wrap samples were taken from a brand new roll, as well as from a 1998, a 2006, and a 1995 fire truck.

Table 24. Asbestos bulk sample results of vermiculite-coated fiberglass strips analyzed by NIOSH 9002 Mod

| Chemical | Sample ID | Sample Description                             | Result (%)                                                         |                                      |

# **6** Conclusions

Of the samples collected at Air Operations, hexavalent chromium, lead, PCBs, and chlorinated dioxins/furans were measured in the following samples:

- Hexavalent chromium was detected in the PBZ air sample from a helicopter mechanic performing heavy aircraft maintenance in the hangar (sample ID HM-1103-13); the exposure result was one order of magnitude below the Cal/OSHA action level and permissible exposure limit (PEL).
- Hexavalent chromium was detected in the two wipe samples collected from Mastinox-coated surfaces on the Bell412 aircraft located inside the hangar; the results were 0.080 μg/cm² for sample ID N14LA-05 and 0.54 μg/cm² for sample ID N14LA-06.
- Hexavalent chromium was detected in all six surface wipe samples collected on the hot part of the Bell412 engines parked on the flight line<sup>1</sup> (sample IDs N18LA-01, N17LA-04, N18LA-02, N120LA-01, N120LA-02, N17LA-03). The results ranged between 0.00076 and 0.0022 μg/cm<sup>2</sup>.
- Lead was detected in five of six surface wipe samples collected on various locations of the aircraft parked on the flight line (sample IDs N120LA-03-A, N822LA-03-A, N120LA-01-A, N120LA-02-A, N822LA-02-A). The detected results ranged between 0.0082 and 0.016 µg/cm<sup>2</sup>.
- Lead was detected in five of six surface wipe samples collected on various locations of the aircraft parked in the hangar (sample IDs N190LA-01-A, N14LA-02-A, N14LA-01-A, N190LA-03-A, N14LA-03-A). The detected results ranged between 0.019 and 0.033 μg/cm<sup>2</sup>.
- PCBs and chlorinated dioxins/furans were detected in the surface wipe samples collected on the horizontal stabilator (sample ID 356-4) and the chin bubble (sample ID 356-5) of the Bell412 parked on the flight line. The PCB TEQ maximum result was 1.2x10<sup>-9</sup> μg/cm<sup>2</sup>, the non-TEQ PCB maximum result was 4.2x10 μg/cm<sup>2</sup>, and the chlorinated dioxin/furan TEQ maximum result was 1.5x10<sup>-8</sup> μg/cm<sup>2</sup>.

In the samples collected at the Breathing Apparatus Shop in Pacoima, benzene, acetaldehyde, formaldehyde, PAHs, lead, PCBs, and chlorinated dioxins/furans were detected:

• Benzene was detected in the PBZ air samples collected from both equipment maintenance workers working in the small-engine repair shop (0.68 mg/m<sup>3</sup> in

57

Recent communication (July 2020) from Pratt Whitney stated that hexavalent chromium could be present on the engine, and that the engine should not be cleaned by blowing air onto the surface.

- sample ID EL0064 and 0.30 mg/m<sup>3</sup> in sample ID EL0139); the exposures were below the Cal/OSHA action level and PEL.
- Acetaldehyde and formaldehyde were detected in the PBZ air samples collected from both equipment maintenance workers working in the small engine repair shop (sample IDs A295581 and A295575). Acetaldehyde detected results (0.027 mg/m³) were three orders of magnitude below the Cal/OSHA PEL, and formaldehyde detected results (0.026 and 0.028 mg/m³ for sample IDs A295581 and A295575, respectively) were one order of magnitude below the Cal/OSHA PEL.
- PAHs were detected in the surface wipe samples from the training air packs (sample IDs ECTC-T-8, ECTC-T-38, NCSO-04), but not from the field air packs.
- PCBs and chlorinated dioxins/furans were detected in the surface wipe samples from the field and training air packs (sample IDs BA-1 and BA-2, respectively). The PCB TEQ maximum result was 1.8x10<sup>-9</sup> μg/cm<sup>2</sup> (training air pack), the non-TEQ PCB maximum result was 2.1x10<sup>-5</sup> μg/cm<sup>2</sup> (field air pack), and the chlorinated dioxin/furan TEQ maximum result was 3.0x10<sup>-8</sup> μg/cm<sup>2</sup> (training air pack).
- Lead was detected on all six surface wipe samples from the training and field air packs (sample IDs ECTC-T-8-A, ECTC-T-38-A, A49996-QUT-185-4-A, A50143-Q-24-5-A, NC50-4-A, AS0421-ENG-21-4-A). The results ranged between 0.013 and 0.048 μg/cm². On the fire hoses, lead was detected on all six surface wipe samples (sample IDs H-01-A, H-02-A, H-03-A, H-04-A, H-05-A, H-06-A). The results ranged between 0.0076 and 0.13 μg/cm².

In the surface wipe samples collected at the Eastern Fire Shop, lead, PCBs, and chlorinated dioxins/furans were detected:

- Lead was detected on all six surface wipe samples collected on various locations of the fire apparatus (sample IDs ENG583-A-1, ENG-558-A-01, ENG159-A-1, ENG-583-A-02, ENG-168-A-01, ENG-558-A-02). The results ranged between 0.030 and 0.54  $\mu$ g/cm<sup>2</sup>.
- PCBs and chlorinated dioxins/furans were detected in the surface wipe samples collected on various locations of the fire apparatus (sample IDs ENG-558-DFP-02, ENG-583-DFP-01, ENG-159-DFP-1, ENG-583-DFP-01, ENG-558-DFP-01). The PCB TEQ maximum result was 5.1x10<sup>-9</sup> μg/cm<sup>2</sup>, the non-TEQ PCB maximum result was 9.4x10<sup>-5</sup> μg/cm<sup>2</sup>, and the chlorinated dioxin/furan TEQ maximum result was 3.0x10<sup>-8</sup> μg/cm<sup>2</sup>, all from sample ID ENG-583-DFP-01 (sampling location: left rear frame at differential).

Of the PBZ air samples collected at the Eastern Fire Shop, the detections included the following:

- Tetrachloroethylene was detected in all six PBZ air samples collected from the fire equipment mechanics, results ranging between 12 and 75 mg/m<sup>3</sup>. All of the measurements were below the Cal/OSHA PEL.
- Cobalt and nickel in welding fumes were detected between two and three orders of magnitude below the Cal/OSHA PEL.
- Diesel particulate as elemental carbon was detected in one PBZ air sample (0.180 mg/m³; sample ID 11405); however, Cal/OSHA has not published a PEL for diesel particulate matter.

The detection of diesel particulate as elemental carbon was the only measured analyte in the eight samples analyzed (six employee PBZ and two area PBZ air samples). Elemental carbon is considered a conservative measure of diesel particulate matter. This result was two orders of magnitude greater than the other sample results. Because elemental carbon is a surrogate for diesel particulate, it is uncertain whether the exposure was caused by diesel emissions or another source of elemental carbon.

Chemicals were not measured in the field blanks above the detection limit or minimum level of quantitation, as applicable to PCBs. The data validation of the analytical data is provided in Attachment 3.

# 7 Next Steps

Task 5 will build on the results of Task 4 and will include calculating the theoretical excess cancer risk from exposure to carcinogenic materials for each SEG determined from Task 2 and toxicity criteria relevant to California risk assessments. The risk assessment will result in an estimate of the increased risk of developing cancer as a result of exposure. This approach involves varying degrees of conservatism, ensuring that cancer risk is not underestimated, which makes it probable that the estimated risk will be overestimated.

For Task 3, Epidemiologic Assessment, employee records are being evaluated for completeness and suitability for a future cancer epidemiology study.

Task 6 may include analyzing public comments, explaining the rationale for specific policy recommendations, and disseminating the study findings to the governor, state legislature, Occupational Safety and Health Standards Board, Los Angeles County Board of Supervisors, and stakeholders in the workers' compensation system.

#### **General Lab Comments**

The results provided in this report relate only to the items tested.

Samples were received in acceptable condition unless otherwise noted.

The following was provided by the client: Sample ID, Collection Date, Sampling Location, Media Type, Sampling Parameter.

Collection Date, Media Type, and Sampling Parameter can potentially affect the validity of the results.

Samples have not been blank corrected unless otherwise noted.

This test report shall not be reproduced, except in full, without written approval of ALS.

ALS provides professional analytical services for all samples submitted. ALS is not in a position to interpret the data and assumes no responsibility for the quality of the samples submitted.

All quality control samples processed with the samples in this report yielded acceptable results unless otherwise noted.

ALS is accredited for specific fields of testing (scopes) in the following testing sectors. The quality system implemented at ALS conforms to accreditation requirements and is applied to all analytical testing performed by ALS. The following table lists testing sector, accreditation body, accreditation number and website. Please contact these accrediting bodies or your ALS project manager for the current scope of accreditation that applies to your analytical testing.

| Testing Sector      | Accreditation Body (Standard)    | Certificate<br>Number | Website                                                                                     |

#### **Definitions**

LOD = Limit of Detection = MDL = Method Detection Limit, A statistical estimate of method/media/instrument sensitivity.

LOQ = Limit of Quantitation = RL = Reporting Limit, A verified value of method/media/instrument sensitivity.

ND = Not Detected, Testing result not detected above the LOD or LOQ.

NA = Not Applicable.

- < Means this testing result is less than the numerical value.
- () This testing result is between the LOD and LOQ and has higher analytical uncertainty than values at or above the LOQ.

#### General Lab Comments

The results provided in this report relate only to the items tested.

Samples were received in acceptable condition unless otherwise noted.

The following was provided by the client: Sample ID, Collection Date, Sampling Location, Media Type, Sampling Parameter.

Collection Date, Media Type, and Sampling Parameter can potentially affect the validity of the results.

Samples have not been blank corrected unless otherwise noted.

This test report shall not be reproduced, except in full, without written approval of ALS.

ALS provides professional analytical services for all samples submitted. ALS is not in a position to interpret the data and assumes no responsibility for the quality of the samples submitted.

All quality control samples processed with the samples in this report yielded acceptable results unless otherwise noted.

ALS is accredited for specific fields of testing (scopes) in the following testing sectors. The quality system implemented at ALS conforms to accreditation requirements and is applied to all analytical testing performed by ALS. The following table lists testing sector, accreditation body, accreditation number and website. Please contact these accrediting bodies or your ALS project manager for the current scope of accreditation that applies to your analytical testing.

| Testing Sector      | Accreditation Body (Standard)    | Certificate<br>Number | Website                                                                                    |

#### **Definitions**

LOD = Limit of Detection = MDL = Method Detection Limit, A statistical estimate of method/media/instrument sensitivity.

LOQ = Limit of Quantitation = RL = Reporting Limit, A verified value of method/media/instrument sensitivity.

ND = Not Detected, Testing result not detected above the LOD or LOQ.

NA = Not Applicable.

- < Means this testing result is less than the numerical value.
- () This testing result is between the LOD and LOQ and has higher analytical uncertainty than values at or above the LOQ.

#### **General Lab Comments**

The results provided in this report relate only to the items tested.

Samples were received in acceptable condition unless otherwise noted.

The following was provided by the client: Sample ID, Collection Date, Sampling Location, Media Type, Sampling Parameter.

Collection Date, Media Type, and Sampling Parameter can potentially affect the validity of the results.

Samples have not been blank corrected unless otherwise noted.

This test report shall not be reproduced, except in full, without written approval of ALS.

ALS provides professional analytical services for all samples submitted. ALS is not in a position to interpret the data and assumes no responsibility for the quality of the samples submitted.

All quality control samples processed with the samples in this report yielded acceptable results unless otherwise noted.

ALS is accredited for specific fields of testing (scopes) in the following testing sectors. The quality system implemented at ALS conforms to accreditation requirements and is applied to all analytical testing performed by ALS. The following table lists testing sector, accreditation body, accreditation number and website. Please contact these accrediting bodies or your ALS project manager for the current scope of accreditation that applies to your analytical testing.

| Testing Sector      | Accreditation Body (Standard)    | Certificate<br>Number | Website                                                                                     |

#### **Definitions**

LOD = Limit of Detection = MDL = Method Detection Limit, A statistical estimate of method/media/instrument sensitivity.

LOQ = Limit of Quantitation = RL = Reporting Limit, A verified value of method/media/instrument sensitivity.

ND = Not Detected, Testing result not detected above the LOD or LOQ.

NA = Not Applicable.

- < Means this testing result is less than the numerical value.
- () This testing result is between the LOD and LOQ and has higher analytical uncertainty than values at or above the LOQ.

#### General Lab Comments

The results provided in this report relate only to the items tested.

Samples were received in acceptable condition unless otherwise noted.

The following was provided by the client: Sample ID, Collection Date, Sampling Location, Media Type, Sampling Parameter.

Collection Date, Media Type, and Sampling Parameter can potentially affect the validity of the results.

Samples have not been blank corrected unless otherwise noted.

This test report shall not be reproduced, except in full, without written approval of ALS.

ALS provides professional analytical services for all samples submitted. ALS is not in a position to interpret the data and assumes no responsibility for the quality of the samples submitted.

All quality control samples processed with the samples in this report yielded acceptable results unless otherwise noted.

ALS is accredited for specific fields of testing (scopes) in the following testing sectors. The quality system implemented at ALS conforms to accreditation requirements and is applied to all analytical testing performed by ALS. The following table lists testing sector, accreditation body, accreditation number and website. Please contact these accrediting bodies or your ALS project manager for the current scope of accreditation that applies to your analytical testing.

| Testing Sector      | Accreditation Body (Standard)       | Certificate<br>Number | Website                                                                                    |

#### **Definitions**

LOD = Limit of Detection = MDL = Method Detection Limit, A statistical estimate of method/media/instrument sensitivity.

LOQ = Limit of Quantitation = RL = Reporting Limit, A verified value of method/media/instrument sensitivity.

ND = Not Detected, Testing result not detected above the LOD or LOQ.

NA = Not Applicable.

- < Means this testing result is less than the numerical value.
- ( ) This testing result is between the LOD and LOQ and has higher analytical uncertainty than values at or above the LOQ.

#### General Lab Comments

The results provided in this report relate only to the items tested.

Samples were received in acceptable condition unless otherwise noted.

The following was provided by the client: Sample ID, Collection Date, Sampling Location, Media Type, Sampling Parameter.

Collection Date, Media Type, and Sampling Parameter can potentially affect the validity of the results.

Samples have not been blank corrected unless otherwise noted.

This test report shall not be reproduced, except in full, without written approval of ALS.

ALS provides professional analytical services for all samples submitted. ALS is not in a position to interpret the data and assumes no responsibility for the quality of the samples submitted.

All quality control samples processed with the samples in this report yielded acceptable results unless otherwise noted.

ALS is accredited for specific fields of testing (scopes) in the following testing sectors. The quality system implemented at ALS conforms to accreditation requirements and is applied to all analytical testing performed by ALS. The following table lists testing sector, accreditation body, accreditation number and website. Please contact these accrediting bodies or your ALS project manager for the current scope of accreditation that applies to your analytical testing.

| Testing Sector      | Accreditation Body (Standard)       | Certificate<br>Number | Website                                                                                    |

#### **Definitions**

LOD = Limit of Detection = MDL = Method Detection Limit, A statistical estimate of method/media/instrument sensitivity.

LOQ = Limit of Quantitation = RL = Reporting Limit, A verified value of method/media/instrument sensitivity.

ND = Not Detected, Testing result not detected above the LOD or LOQ.

NA = Not Applicable.

- < Means this testing result is less than the numerical value.
- ( ) This testing result is between the LOD and LOQ and has higher analytical uncertainty than values at or above the LOQ.
